Masterproef voorgelegd voor het behalen van de graad master in de richting Meertalige
Communicatie (Nederlands, Engels, Italiaans)

Academiejaar: 2016 - 2017

Acknowledgements

I would like to express my sincere gratitude to my promotor Prof. Dr. Veronique Hoste, who gave me a lot of help during the process of this master's thesis. Since I had not much prior knowledge on emotion and sentiment detection, she provided me with a number of helpful articles and books and explained some of the concepts. Because of that, I was able to deliver this thesis and expand my knowledge on emotion and sentiment analysis.

I am also thankful for the help I received from the LT3 department, especially to retrieve the tweets for my corpus and build the machine-learning system.

Lastly, I would also like to thank my parents for giving me the opportunity to study and to encourage me whenever this was needed.

Abstract

In recent years, many research was performed on sentiment analysis, on a lexicon-based as well as on a learning-based level (Balahur 2011, Pontiki et al. 2016, Van Hee, Lefever and Hoste 2015). Emotion analysis may give a more profound overview of the feelings of the author, but is still in its infancy. This study aims to determine the reputation of Donald J. Trump by investigating the mostly used emotions in tweets about him during the previous American elections. It also aims to build an emotion detection system on the basis of machine-learning. A Twitter corpus of 556 tweets divided over 7 important moments during and after the American elections was annotated for emotion, emotion words, implicitnessn sentiment, target and irony. In total, sixteen emotions were extracted from the emotion models of Ekman (1992), Suet Yan and Turtle (2016) and Russel (1980). The most prominent annotated emotions throughout the corpus are 'frustration' and 'disgust'. It was also found that the largest number of tweets were targeted against Donald Trump and that his reputation is rather negative on Twitter. From the annotated corpus a small machine learning system was built on the basis of character bigrams. This system showed promising results and may be a basis for future work on emotion detection.

Keywords: emotion detection, reputation, Twitter, Donald Trump

1. Introduction

In recent years, social media have become an increasingly important means of communication throughout the world, not only for personal communication, but also for business communication (Wright and Hinson, 2014).

More and more companies and organisations are using social media to communicate with their stakeholders and consumers (Mc Corkindale & Di Staso 2013, p.497). Carroll (2013, p.6) argued that the corporate reputation may be damaged when people think that the company does not listen to their issues and messages. On top of that, since social media have become increasingly important, stakeholders can obtain a lot of information about a company, and converse with each other about that matter or even with the company itself (Varey, 2013, p.114). Therefore, companies need to be aware of the importance of social media and the communication with their stakeholders.

Since the importance of social media has risen, research on the topic has increased. Especially Twitter has been the subject of extensive research and analysis (Balahur 2011, Balikas & Amini 2016, Jin et al. 2014). Wright and Hinson (2014) found in that sense that Twitter has become more important than Facebook as a means for public relations. This may be due to the fact that on Facebook people tend to follow friends or people with whom they have a strong or weak personal relationship. On Twitter, however, they tend to follow others with whom they do not have that personal connection. Because of this, businesses are able to connect with people to whom they do not have a personal connection (Mc Corkindale & Di Staso 2013, p.506).

Not only companies, but also public figures, such as politicians, use social media to communicate with their voters and the general public. In this sense, Tumasjan et al (2010), found that the number of tweets that talk about a particular party reproduce the election result.

Many of the recent works regarding Twitter analysis have concentrated on sentiment analysis, which categorises tweets as positive, negative or neutral (Balikas & Amini 2016, Lango, Brzezinski & Stefanowski 2016). Nevertheless, although it is already possible to determine sentiment on an aspect based level, this does not give insights into the emotions people are uttering on social media. The study of emotion detection may open up more possibilities for research of, for example, crisis situations (Briones et al. 2011, Jin et al. 2014) and for Online Reputation Management.

Nevertheless, the number of possible emotions to analyse differs from research to research. Some researchers concentrate on the six basic emotions that were identified by Ekman (1992), namely 'anger', 'disgust', 'fear', 'sadness', 'joy' and 'surprise', such as Strapparava and Mihalcea (2007) and Bellegarda (2007). Other studies analyse more possible emotions, such as that from Desmet and Hoste

(2013) where they analysed fifteen different types of emotions that were used in suicide notes. Suet Yan and Turtle (2016) even performed fine-grained emotion analysis for 28 emotions. Another possible way to analyse emotions is to put them on a continuum scale with a small number of strict emotions, rather than categorising them as different discrete types of emotions,. This is for example the case in the study of Jin et al. (2014), who ranked emotions on an attribution scale instead of a positive-negative scale. Jin et al. differentiate between three types of crisis emotions: attribution-independent crisis emotions ('anxiety', 'fear', 'apprehension' and 'sympathy'), internal-attribution-dependent crisis emotions ('guilt', 'embarrassment' and 'shame') and crisis emotions ('disgust', 'contempt', 'anger' and 'sadness').

Given the fact that most of the previous research has concentrated on sentiment detection and that the field of emotion detection is still in its infancy, this study will concentrate on the type of emotions expressed in tweets about a political figure, namely U.S. President Donald J. Trump, during and shortly after the American elections (28 September until 11 November).

In addition, it will determine whether the reputation of Donald Trump is rather positive or negative on Twitter by labelling both the sentiments and emotions expressed in tweets. It will also discuss the favourability of Donald Trump as well as his opponent, Hillary Clinton. The aim is to see which emotions are most present in this type of political tweets. Finally, we will also discuss the performance of a machine learning system that was trained on 556 tweets to categorise the emotion of new unseen tweets.

The rest of this master's thesis is organised as follows: Section 2 gives a non-exhaustive overview of the related works on sentiment and emotion analysis. A part about research on reputation management is also included. In section 3 there is an overview of the methodology that was used for this study, including the research questions, the emotions used in this study and an overview of the important moments during the American elections. The last part of this section will be devoted to a description of the learning based system that was tested for this corpus. Section 4 provides an extensive overview of the analysis of the annotated corpus and the performance of the system. The last section details the conclusion and the discussion of this master's thesis.

2. Related works

2.1 Sentiment and emotion analysis

2.1.1 Sentiment analysis

The interest of analysing instances on the internet, especially on social media such as Twitter, has increased in recent years. Many of the works concentrate on sentiment analysis, meaning that the instances are categorised as positive, negative and/or neutral. There are two main approaches towards sentiment analysis, viz. the lexicon-based and the learning-based approach or supervised approach (Liu 2012).

2.1.1.1 Lexicon-based approach

The lexicon-based approach makes usage of a lexicon of words that are labelled either positive, negative or neutral. When analysing a new instance, for example a tweet, the number of positive and negative words that appear in the corpus are counted. If the tweet contains more negative words than positive it is classified as negative, and vice versa. This method has been used for sentiment analysis by various researchers (Andreevskaia & Bergler 2006, Esuli & Sebastiani 2005, Esuli & Sebastiani 2006, Esuli & Sebastiani 2007, Kamps et al. 2004).

There exist a number of lexicons that researchers can use for their lexicon-based approach. In this part, WordNet (Fellbaum et al. 1993), SentiWordNet (Baccianella, Esuli and Sebastiani 2010), WordNet-Affect (Strapparava & Valitutti 2004) and MPQA (Wiebe, Wilson and Cardie 2005) will be discussed.

WordNet is an extensive English lexicon which contains nouns, adverbs, adjectives and verbs. Words can be grouped together in lists, called synsets, if they have a relation of synonymy. Nevertheless, they are not attributed with a sentiment.

SentiWordNet also ranks words into synsets. Afterwards, each word is given a numerical sentiment score. As words can be ranked in more than one synset, they can be given a different sentiment, based on the sense of the word. In that case, it is advisable to include WSD (Word Sense Disambiguation) to be able to find the most suitable solution.

WordNet-Affect uses the English lexicon WordNet as a basis and enhances it by assigning affective labels (called A-labels) to the words. In total, there are 11 A-labels: 'emotion', 'mood', 'trait', 'cognitive state', 'physical state', 'hedonic signal', 'emotion-eliciting situation', 'emotional response', 'behaviour', 'attitude' and 'sensation'.

MPQA or Multi-Perspective Question Answering Corpus is a subjectivity lexicon of 8.222 terms. Each of the words are linked with a certain polarity (positive, negative or neutral) and its polarity intensity (strong or weak).

These lexicons have been used by many researchers to determine sentiment in text. Andreevskaia and Bergler (2006) applied WordNet as a lexicon for their graded determination of sentiment. This means that a term can vary from 'fuzzy' to 'probabilistic', referring to the degree of positivity or negativity.

Musto, Semeraro & Polignano (2014) analysed the above-mentioned lexica on data of SemEval 2013. The best results were obtained by SentiWordNet and MPQA, while WordNet-Affect obtained the lowest scores.

Esuli and Sebastiani (2005) used the online definitions of words (glosses) to determine the sentiment of a word. In 2006, they tried to determine whether terms had a subjective connotation (negative or positive) or solely an objective connotation.

The lexicon-based method for sentiment analysis was also used by Kim and Hovy (2004). They included synonyms and antonyms of words in WordNet to a hand-picked seed list, applying the same sentiment for synonyms and the opposite sentiment for antonyms.

In addition, Ding, Liu and S. Yu (2008) used the lexicon of WordNet to set up a lexicon-based system, called Opinion Observer, to deal with context dependent words. They tried to solve a few problems that exist in sentiment analysis, such as the occurrence of positive and negative words in the same sentence.

The problem with deriving the sentiment from a text based on the sentiment of the words is that, sometimes, positive words can be made negative and vice versa. In the sentence 'I am not happy', 'happy' would be labelled as positive, but the sentence in itself is negative due to the negative particle 'not'. These negative elements, along with adverbs, verbs, subordinators etc. that can make a sentence negative, have been called 'valence shifters' by Polanyi and Zaenen (2006).

Taboada et al. (2011) used the Semantic Orientation CALculator (SO-CAL), which consists of 'Epinions 1', a sentiment dictionary extracted from 400 texts, including the strength and the negation of the instances. The calculator was tested on reviews of different domains and was found to be consistent on unseen texts.

In the previously-mentioned work of Musto, Semeraro and Polignano (2014), sentences are split in phrases on the basis of so-called 'splitting-cues'. These cues can either be punctuation, adverbs or a certain type of conjunction.

Nevertheless, there exists also another problem with sentiment analysis on the basis of lexica. Whereas lexicon-based sentiment analysis systems are still heavily used in commercial applications, due to their ability to quickly process large volumes of texts, their quality heavily depends on the quality of the lexicons they use. Furthermore, apart from the difficulties they experience when handling negation, but also modality, they completely ignore lexical ambiguity. Depending on the context, some words can have a negative or a positive connotation. The verb 'suck', for example, is usually associated with a negative connotation. However, in a review on a vacuum cleaner, this word might receive a positive connotation. Furthermore, sentences can also convey sentiment without the usage of sentiment words, e.g. "This cell phone needs to be charged twice a day". (Liu 2012, pp.12-13; Van de Kauter, Desmet & Hoste 2015).

2.1.1.2 Learning-based approach

As the usage of a lexicon may sometimes not give sufficient information for effective sentiment analysis, many researchers today prefer the learning-based approach.

The learning-based or machine learning approach can still use a lexicon with the predefined sentiment classification of words as a feature, but it also makes usage of a training corpus with a high number of instances, for example tweets. These instances have been annotated as positive, negative or neutral. On the basis of this information, the computer will analyse the sentences and 'learn' how to categorise other, unseen, sentences, hence the name 'machine learning approach'. The computer will thus categorise new sentences as positive, negative or neutral based on the information it has inferred from the manually annotated sentences. The machine learning approach is increasingly being used by scholars for sentiment analysis.

In this method, information on a given text is encoded in a so-called feature vector. This information can be lexical, semantic, syntactic or another type of information. N-grams, for example bigrams or trigrams, are sequences of two or three tokens or characters, and are an often used feature type (Balikas & Amini 2016, Severyn et al. 2014, Lango, Brzezinski, & Stefanowski 2016, Van Hee, Lefever & Hoste 2015). Especially character N-grams have shown to work well on social media data, as they are able to determine a word that is spelled incorrectly.

Word shape features tell something about a word when it has for example character flooding, which means that a certain character is repeated more than two times in a token (e.g. haaaaaappy). There also exists punctuation flooding, which means that an exclamation or question mark is repeated several times (e.g. ???!?) (Van Hee et al. 2014). The number of capitalised words can also give information about a particular instance. In the case of Twitter analysis, a feature can also be the number of hashtags that are used in the tweet (Van Hee et al. 2014, p. 407).

In addition, as described above, a lexicon may also be used as a feature for the machine learning strategy. Then, the overall polarity can be identified on the basis of the number of positive, negative and neutral words on the average of the text length. Syntactic features, such as part of speech tags (POS), can also be added to analyse the function of a set of tokens within a sentence (Van Hee et al. 2014, p.408). Another important feature is the indication of Named Entity Features, which are used to determine the proper names used in the instances (Van Hee et al. 2014, p.408). In the case of our corpus, this can be Trump, Obama, Clinton and so on.

The number of works on sentiment analysis and the machine learning strategy is growing rapidly. As an example, already in 2002, Pang, Lee and Vaithyanathan examined the sentiment of film reviews using the learning algorithms SVM (Support Vector Machine), Naïve Bayes and Maximum Entropy Classification. In addition, Wilson, Wiebe and Hoffmann (2008) tackled the problem of contextual polarity in which a word's polarity is changed by its context. Athar (2011) used a manually annotated corpus to determine the sentiment of citations in scientific texts.

Furthermore, the research that was performed in the SemEval (Semantic Evaluation) workshops in the past few years has also provided a lot of advancements in sentiment analysis and other aspects of semantic analysis.

For SemEval-2014 (Nakov & Zesch 2014), researchers could choose from different shared tasks, among which aspect based sentiment analysis (ABSA) and sentiment analysis in Twitter.

SemEval-2015 (Nakov et al. 2015) focused on 17 tasks divided over 5 main tracks, among which also a sentiment track. With SemEval-2016, Pontiki et al. (2016) organised for the third time a shared task on aspect based sentiment analysis. 7 domains and 8 languages were included in this study, which focused on sentence-level as well as on text-level analysis. This is an example of the fact that research in sentiment classification changes rapidly.

In the early work on sentiment analysis, sentiment was analysed on text or document level (Pang, Lee and Vaithyanathan 2002), which means that the overall sentiment for the entire text or document is determined. Below text level, sentiment can also be determined on sentence or sub-sentence level. Both text or document level analysis and sentence or tweet analysis are often referred to as coarse-grained analysis. As this methodology is not very informative when sentiment is expressed for more than one subject, there is a recent tendency to perform a more fine-grained sentiment analysis. This analysis, also called aspect based sentiment analysis, assumes that the target and the sentiment are the constitutive elements of an opinion (Liu 2012, p. 11). In the sentence: "This Toshiba laptop is really fast but its sound quality is quite terrible", the person expresses a positive sentiment towards the fact

that the laptop is fast and a negative sentiment towards the sound quality (target). Nevertheless, although it is now possible to perform research on aspect level, there still exist some challenges.

For aspect-based sentiment analysis, the challenge lies in creating a system that works domain-independently, while nowadays studies concentrate on the same specific domains such as electronics or restaurants (Pontiki et al. 2016, Balahur 2011).

On top of that, it should be noted that Twitter messages are user-generated content, meaning that they may contain misspellings, abbreviations, acronyms (e.g. LOL (Laughing Out Loud, YOLO (You Only Live Once)) or slang. Rosenthal, Mc Keown and Agarwal (2014) tried to solve this problem by using an acronym dictionary together with Wiktionary and an emoticon dictionary, to improve sentiment detection.

Another challenge is the accurate classification of figurative tweets. Van Hee, Lefever, and Hoste (2015) performed fine-grained sentiment analysis on figurative tweets and studied how sarcasm or irony may affect that analysis. A similar observation was made by González-Ibañez, Muresan and Wacholder (2011), who used a corpus with tweets that were manually-labelled as sarcastic to compare these with non-sarcastic utterances. Their conclusion was that sarcasm is difficult to detect by both the machine learning techniques and by humans.

2.1.2 Emotion

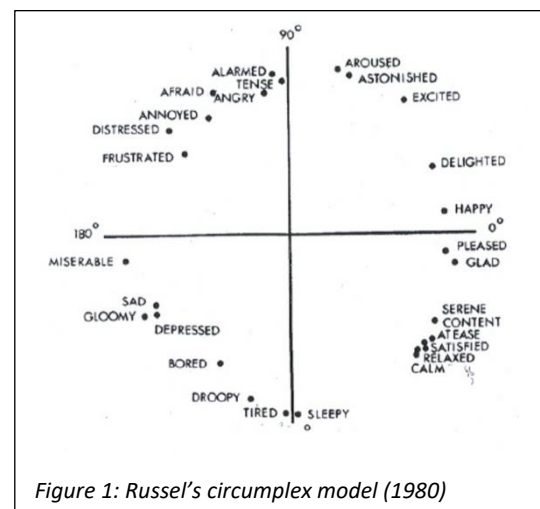

Recently, researchers have not only been interested in fine-grained sentiment analysis, but have started to include emotion analysis to their field of research as this would give more information about an instance than the categories present in sentiment analysis (Strapparava & Mihalcea 2007, p.70, Suet Yan & Turtle 2016, p.73).

Emotion analysis is not only important from a scientific point of view, but also for business intelligence, as it may provide a better understanding of customers' opinions (Culotta & Cutler 2016). For emotion detection, there is also the possibility of a lexicon-based or a learning-based approach.

2.1.2.1 Emotion categories

Whereas there are only up to five possible categories in sentiment classification ((very) positive, (very) negative and neutral), the classification of emotions is not yet determined.

Emotions can for example be ranked on a continuum (a scale), which is called emotional dimension (Francisco & Gervás 2013, p. 4). Russel's circumplex model (Russel 1980, see Figure 1), for example, ranks emotions on a scale from unpleasant to pleasant, on the horizontal axis, and a scale from activation (arousal) to deactivation (sleep), on the vertical axis. In Russel's model, emotions are then seen and measured as a degree in a circle of 360 degrees. 'Happy', for example, is situated at 7.8°. At this point, augmenting the degree means that the value of activation will increase, while that of pleasantness will decrease. Emotions that are the exact opposites of each other, will have a difference of 180 degrees (Russel 1980, p.116)

One can also see opposites in the quadrants. 'Excited', being the combination of a high level of pleasure and activation, for example, can be seen as the opposite of 'depressed', the latter being the combination of low pleasure and low activation or arousal. In the same study of Russel (1980), it was also tested whether people would be able to determine the position of the emotions without any prior knowledge. Participants were asked to determine the place of 28 emotions in 8 categories. These eight categories were the extremes of the circle, being 'aroused', 'sleepy', 'pleased', 'miserable', 'depressed', 'excited', 'distressed' and 'content'. In another exercise, 10 out of 36 participants successfully arranged the eight emotion categories on a circle, where words opposite of each other represented opposite emotions (such as 'excitement' and 'depression').

Emotions can also be viewed as emotional categories (Francisco & Gervás 2013, p. 4), which means that discrete classes with specific types of emotions are identified. For that discrete identification of emotions, there is for example the theory of Ekman (1992). He identified six basic and universal emotions: 'anger', 'sadness', 'joy', 'surprise', 'fear' and 'disgust'. These emotions have nine characteristics in common: distinctive universal signals (facial expressions), presence in other primates, distinctive physiology, distinctive universals in antecedent events, coherence among emotional response, quick onset, brief duration, automatic appraisal and unbidden occurrence (p. 175).

2.1.2.2 Automatic emotion detection

Strapparava and Mihalcea (2007) tried to identify the six basic emotions of Ekman in their machine learning analysis of newspaper headlines. A valence scale that went from 'highly negative' to 'highly positive' was also implemented. Also Chaffar and Inkpen (2011) used the emotions determined by Ekman in a machine-learning method to determine the emotion of newspaper headlines, fairy tales and blogs, using a number of features, such as bag of words.

Nevertheless, not all researchers adhere to the theory of Ekman and also identify other possible types of emotions. When studying the emotions of suicidal notes, Desmet and Hoste (2013) found fifteen different types, including 'guilt' and 'hopelessness'. Yet, in the study of Brynielsson et al. (2014) only four different emotions ('positive' ('happiness'), 'anger', 'fear' or 'other') were annotated for the tweets about hurricane Sandy. Suet Yan and Turtle (2016) used a manually-annotated corpus with 28 different emotion categories to train a learning algorithm for their fine-grained emotion analysis.

Nonetheless, as most of the studies on emotion analysis make usage of an annotated corpus, it is also possible to implement a lexicon-based approach. Staiano and Guerini (2014) built Depeche Mood, which is a lexicon of 37,000 words that can be used for the analysis of emotions. Bandhakavi et al. (2014) made usage of an emotion- labelled corpus that can be used to develop a lexicon automatically. The results for the data in the experiment show that the system which relied on the automatically-generated lexicon leads to a better classification performance in comparison with other manually-built lexicons, such as WordnetAffect Affect (Strapparava & Valitutti 2004). Another interesting study was performed by Pool and Nissim (2016), who used the new reaction possibilities on Facebook posts as an emotion label to help determine the emotion of a particular post. A widely used lexicon is SenticNet (Cambria & Houssain, 2012). This is a lexicon with over 50, 000 concepts that are linked with four possible dimensions ('pleasantness', 'attention', 'sensitivity' and 'aptitude').

In this study, we will analyse the emotions in tweets about Donald Trump on the basis of 16 emotion categories. These emotions were extracted from the emotion models from Russel (1980), Ekman

(1992) and Suet Yan (2016). A list and a more detailed motivation for the choice of these emotions can be found in section 3.3.2.

2.2 Reputation

Emotion analysis can give the opportunity for businesses to monitor the emotions of their customers. Reputational damage may be averted when they respond effectively and rapidly to these emotions (Poels & Hoste 2015, p.49). This section intends to provide a non-exhaustive overview of a number of important and recent works and articles on corporate reputation and Online Reputation Management.

Carroll defines reputation as “how a person views another person, an industry or even a country and that a certain reputation can change according to events on or contexts.” (2013, p. 15).

In 2011, Carroll, Greyser and Schreiber described the different types of reputation in the ACID framework (p. 467): the actual reputation, the communicated reputation, the conceived (or perceived) reputation, the construed reputation, the covenanted reputation, the ideal reputation and the desired reputation.

The type of reputation this master’s thesis will take into account is that of the perceived or conceived reputation, which is the reputation of how a company- or in this case Donald Trump- is conceived by people, for instance Twitter users.

Before the internet and Web 2.0, when people had a negative experience with a company or a product, there were only a few options to share that experience. They could write a letter or talk about the negative experience with friends and family, who could then retell the story to others. Now, in the era of Web 2.0, people have the possibility to tell their negative experience to the rest of the world in just a few clicks. Social media, such as Twitter, give the opportunity to spread negative or positive opinions about a company or a person.

Varey (2013) argues that ‘word of mouth’ in the era of internet has become ‘word of mouse’, meaning that messages are not told from one person to another but they are told simultaneously to a large group of impersonal persons (p. 114). In 2009, Jansen et al. found that microblogging, including Twitter, is an important medium for online word of mouth communication about companies and that this has implications on their marketing strategy. As a consequence, the online reputation of an entity can be considered the real reputation of that entity (Fetik & Thompson 2010, p. 6).

Wright and Hinson (2014) analysed social media and their relations with public relations for nine years. They found that since 2014 Twitter has surpassed Facebook as the social medium that is most used for public relations. On top of that, the study revealed that the importance of mainstream news media is weakening in favour of social media. O’Connor and Balasubramanyan (2010) compared polls on public

opinion with tweets about the same topic. Sentiment analysis of the tweets indicated that there was a high correlation (up to eighty per cent) between the tweets and the opinion polls.

Park and Min Lee (2007) studied the possible effects that online news forums might have on corporate reputation. They found that multiple positive comments about a company on news sites provided for a higher positive perception. On the other hand, they found that only one negative comment was enough to have a negative impact on the corporate reputation.

Good reputation management should take into account the enormous impact and influence of social media. Because of that, Online Reputation Management has become increasingly important over the past few years (Mc Corkindale & Di Staso 2013). Tracking a company's or, in this case, a public figure's reputation manually takes a lot of time, money and effort. In order to make this task less time-consuming, researchers have been searching for ways to automatically track the online reputation of a company or business. In recent years, Social Media Monitoring tools have become more popular. CX Social (<http://cxsocial.clarabridge.com>) for example, (Ghent, Belgium) tracks the presence and conversations about certain companies on social media. Yet, there is still a lot of research needed to create real Online Reputation Management (ORM) systems. To this end, RepLab was created, which is a competition that evaluates ORM's on certain aspects, mainly for Twitter. In RepLab2014, the task included the classification of the dimensions of reputations (including products and services, leadership, citizenship, governance, etc. and author profiling) (Amigó et al. 2014).

Also outside the framework of the RepLab competition, researchers have tried to measure the reputation of a company or person. Cossu et al. (2014) analysed the reputation of François Hollande and Nicolas Sarkozy in French tweets using specialists in political science as their main annotators. The reputation of both Hollande and Sarkozy was measured before, during and after the presidential elections of May 2012. Their aim was to make an automatic reputation monitoring system for the French language and French entities, where it was seen that the negativity against François Hollande increases to 79 per cent in the months after his election.

Perez-Tellez et al. (2011) did research on automatically determining whether content is useful for reputation monitoring tools or not. This means that tweets had to be divided into customer tweets and tweets that were not related to a particular company. Lynch and Cunningham (2014) performed a similar study when they wanted to label tweets as coming from expert sources or from customers.

El Marrakchi, Bensaid and Bellafkih (2015) made a Social Media Monitoring Tool that also provided a reputation score, using sentiment and context analysis. Cossu et al. (2015) did research on reputation alert, which alerts whether a comment on Twitter has a considerable implication for the reputation of a company. This alert could, for example, be triggered on the basis of the followers, type and number

of comments of the tweet author by means of author profiling. The profiling combined manual expert annotations and simple machine learning techniques which showed good results on unseen data.

Nevertheless, up until now, researchers have not linked emotion detection with reputation or a Reputation Monitoring Tool. The aim of this master's thesis is to assess the reputation of President Donald J. Trump at critical moments before, during and after the presidential election through annotations of the emotions expressed in tweets about Donald Trump. Furthermore, we investigate the feasibility of automatically detecting these emotions by evaluating the performance of a simple machine learning system for emotion classification trained on our manually labelled corpus.

3. Methodology

This section will give an overview of the method of this study. First, the research questions will be stated, followed by an explanation of the annotation process and a description of the corpus. Further, we give an overview of the moments that were analysed in the corpus and of the emotions that could be indicated during the annotation process. The last part is a description of the machine learning system that was set up for this master's thesis.

3.1 Research questions

The aim of this study is to investigate a few research questions on the basis of a manually labelled corpus. To answer our main research question "What is the reputation of Donald Trump on Twitter?", we formulated the following smaller research questions:

1. What are the typical emotions expressed in political tweets?
2. Are emotions lexicalised? If so, how?
3. In combination with which emotion is irony most present?
4. Is there a correlation between sentiment and emotion?
5. How well does the machine learning system work?

3.2 Annotation process

To allow for a thorough corpus analysis and the development of an automated emotion detection system, we annotated a corpus of tweets about Donald Trump. The tweets were annotated on a number of characteristics (see appendix I for annotation guidelines, appendix II for a description of the corpus and appendix IV for the corpus):

1. whether the tweet contained an emotion or not

Tweet 168: @realDonaldTrump There is no evidence of corruption after decades of investigations, but facts don't matter to #trump. (emotion?: 'yes')

2. which emotion the tweet contained

Tweet 181: Fed up #NeverHillary #NeverTrump (emotion: 'frustration')

3. which words described the emotion

Tweet 328: @WSJ #ElectionNight #Trump shame on you Americans! (words emotion: 'shame on you')

4. the explicit target

Tweet 192: The media (propaganda) is a wake up call to this country!we do not want to live in a communist country!vote #Trump (target: 'the media')

5. the implied target

Tweet 9: @JPE_814: Saw a girl wearing a #MakeAmericaGreatAgain hat on my way to class. At least she has some brains! (implied target: 'Trump')

6. whether the emotion was conveyed implicitly or not

Tweet 11: SupermanHotMale: #BOOM|I love my @FLOTUS and I love when she speaks truth to #Trump!!! (implicit?: 'no')

7. modifiers that made the emotion weaker or stronger

Tweet 55: I really dislike #Trump and all of his Children Of The Corn looking offspring. (That's my contribution to Eric Trump trending). (modifier: 'really')

8. the second emotion of the tweet (if appropriate)

Tweet 57: I now have 3 #democrat friends joining the #TrumpTrain #TrumpStrong #MAGA #TrumpPence16 thanks #Kaine for opening their eyes! (second emotion: 'gratitude')

9. number 3-7 about the second emotion

Tweet 75: You know I can't understand how #NeverTrump'ers can hate on #Pence. He is the absolute best man for the VP, maybe even future Pres...(second emotion: 'admiration'; words emotion: 'the absolute best man'; target: '#Pence'; implied target: 'Pence'; implicit?: 'no'; modifier: 'absolute')

10. whether the tweet contained irony or not

Tweet 83: Oh the debates 'sigh' I love the African Americans... oh and the Latinos and the Hispanics. #Trump is such a lovable oaf (insert heavy sarcasm) (irony?: 'yes')

11. the first sentiment of the tweet

Tweet 81: #Trump There was nothing in Trump's debate performance that widened his appeal to independents. Quite the opposite they find him frightening (first sentiment: 'negative')

12. the second sentiment of the tweet

Tweet 85: @ShtPaperBrand: #TRUMP HAD THE #ANGER AND #AGGRESSION #TONIGHT #DEBATE HE #WINS WITH #KO #KNOCKOUTS #VICTORY - #THISTIME #TRUMPWON #HANDSDOWN #BABY #WIN !! (second emotion: 'very positive')

13. the words of the first sentiment

Tweet 94: #Trump lies so easily. Lies and hatred roll off his tongue. Trump is nauseating. Truly a hideous person. @dncpress @DFAaction #bully (words sentiment: 'lies', 'hatred', 'nauseating', 'hideous'; '#bully')

14. the words of the second sentiment

Tweet 95: Like Lyin Trump the only thing you need do for me @tschanuth is fek off @realDonaldTrump #NEVERTRUMP #UNFIT will NEVER BE PRESIDENT (words sentiment: 'lyin')

15. of whom the Tweet author would be in favour or not

Tweet 120: Apparently admitting to sexual crimes is just locker room talk,, #nevertrump (favourability: 'not Donald Trump')

3.3 Corpus

In total, the final corpus consists of 556 tweets. The tweets were retrieved between 28 September and 11 November on the basis of a number of hashtags that were trending at that time (see further). In this period, there was a crawl every two days, with a limit of 30,000 tweets. Later, these tweets were cleaned, which means that html tags were left out. Tweets that appeared twice or more, were also deleted from the initial corpus, which ultimately led to 290,000 tweets.

The following is an indication of the number of tweets that was retrieved for each of the hashtags.

#NoTrump: 477	#DonaldDeplorable: 76
#TrumpHate: 54	#Trump: 100,840
#DumpTrump: 5,445	#MakeAmericaGreatAgain: 19,199
#MakeDonaldDrumpfAgain: 318	#TrumpTrain: 33,619
#LoveTrumpsHate: 3,483	#TrumpPence2016: 4,593
#NeverTrump: 33,733	#TrumpRally: 318

As a corpus of 290,000 tweets would have been too time-consuming to annotate, this initial corpus was reduced on the basis of important moments during the American presidential election. In total, seven important moments during the election were chosen to see whether these moments had an impact on the tweets. These moments can either be presidential debates, scandals or the election itself, and are further explained in the next section (3.3.1). For each of the moments, 80 tweets were chosen according to the following process: for each particular moment, the total number of tweets (e.g. 24,000) was divided through 80 (300), meaning that every 300th tweet was included in the final corpus. Tweets that contained URL's were not included in the corpus. If the 300th tweet contained an URL, the next (or even the one next to that) was added to the final corpus. In the final corpus some tweets had to be deleted as they still contained a URL. This eventually led to a corpus of 556 tweets that needed to be annotated.

3.3.1 Important moments during the American elections

The tweets in the corpus were chosen on the basis of a number of important moments during or after the American presidential elections. These moments are explained further in this section. However, sometimes, it was not possible to retrieve the tweets of an exact day. This was mostly because tweets were limited to 30, 000 per day, which means that sometimes no tweets were retrieved after 8 o'clock in the morning. If the event (for example a debate) happened in the evening, it was decided to retrieve the tweets from the next day. Yet, sometimes tweets were not retrieved for several days, because of a technical problem. We selected the following seven important moments for our study:

First debate and following days

The first important moment is that of the first presidential debate on 26 September 2016 (Election Central s.d.). Yet, as tweets were not retrieved on that day, it was decided to analyse tweets in the run-up to the second presidential debate. This means that on 28, 29 and 30 September and 3, 4, 5, 6 and 7 October tweets were retrieved. For each day, ten tweets were retrieved. This was done according to the same process which is described in the section above (3.3).

Second debate and leaking of Trump's tape

The Second presidential debate between Hillary Clinton and Donald Trump was held on 9 October 2016 (Election Central s.d.). The corpus contains eighty tweets that were retrieved on 10 October. As no tweets could be retrieved on 8 October, the morning after the release of Trump's tape (The Washington Post, 8.10.2016), it was also decided that the tweets of 10 October would be used to analyse the reaction on the leaking of the tape of Donald Trump. On this 2005-tape, Trump is heard boasting about using his celebrity status to seduce and touch women, which caused a lot of disgust.

Third debate

The Third presidential debate was held on 19 October 2016. During this debate, Donald Trump announced that he would accept election results only if he won (NBC News, 20.10.2016). As no tweets were retrieved between 20 and 24 October, it was decided to take the tweets on 19 October, the morning before the third debate.

F.B.I investigation Clinton

On 28 October 2016, the F.B.I announced that it would re-open the investigation into the private e-mails of Hillary Clinton (The Washington Post, 28.10.2016). The investigation involved the usage of a private server rather than the federal e-mail server which she should have used for classified information. As the investigation was re-opened just two weeks before the presidential election, this

caused a lot of controversy and Trump supporters began saying phrases like 'Lock her up'. As no tweets were retrieved on 29 and 30 October, it was decided to examine tweets retrieved on 31 October.

Election day

On 8 November, Americans had to vote who they wanted as their next president (The Huffington Post, 01.04.2016). Tweets were retrieved on 8 November to show the suspense before the announcement of the winner of the American elections.

Election result

The final election result was announced on 8 November 11:40 p.m. PT (New York Times, 8.11.2016). Tweets about the reactions were retrieved on 9 November.

Protests after the election result

Many Americans did not want to accept the election result and started protests and riots after the announcement. The protests took place all across America in which many protesters shouted 'Not my President' (The New York Times, 9.11.2016). Reactions on these protests and also on the election result were retrieved on 11 November.

3.3.2 Emotions in this study

For this study, the annotator had to indicate which emotion was conveyed in each of the tweets. The list of emotions the annotator could choose from was composed of the sixteen following emotions:

'Anger', 'disgust', 'joy', 'surprise', 'sadness', 'fear', 'frustration', 'satisfaction', 'admiration', 'conviction', 'doubt', 'hope', 'regret', 'gratitude', 'love' and 'indifference'

These emotions were extracted from the emotion models of Russel (1980), Ekman (1992) and Suet Yan & Turtle (2016).

Initially, the aim of this study was to annotate tweets on the basis of Ekman's emotion model (1992). He identified six basic and universal emotions ('anger', 'sadness', 'joy', 'surprise', 'fear' and 'disgust') on the basis of facial expressions. A random test corpus of 73 tweets about Donald Trump was created and annotated on the basis of this model.

Yet, it was found that some of the tweets could not be annotated on the basis of Ekman’s classification. For example, many of the tweets conveyed the emotion ‘frustration’, but this emotion is not included in Ekman’s model. Overall, 60 per cent of the tweets in the test corpus could not be annotated or could only be annotated partially. Therefore, the emotion models of Russel (1980) and Suet Yan & Turtle (2016) were added to the six emotions of Ekman.

The emotion model of Russel (1980), in contrast to Ekman, is a dimensional framework. It is called the circumplex model, and ranks emotions on a scale from unpleasant to pleasant (valence) and a scale from activation (or arousal) to deactivation (see section 2.1.2.1). Not all emotions in this model were used for the annotation. As the emotions in each of the four corners are closely related to each other, it was decided to select one emotion in each corner: ‘happy’, ‘sad’, ‘frustrated’ and ‘satisfied’. As the emotions ‘happy’ and ‘sad’ were already included in the model of Ekman, they were not included a second time.

Suet Yan & Turtle (2016) used a manually annotated corpus of tweets with 28 different emotion categories.

Class	n	%
Admiration	132	2.38
Amusement	216	3.89
Anger	409	7.37
Boredom	10	0.18
Confidence	15	0.27
Curiosity	27	0.49
Desperation	7	0.13
Doubt	44	0.79
Excitement	228	4.11
Exhaustion	7	0.13
Fascination	47	0.85
Fear	65	1.17
Gratitude	176	3.17
Happiness	697	12.55
Hate	52	0.94
Hope	132	2.38
Indifference	24	0.43
Inspiration	16	0.29
Jealousy	5	0.09
Longing	27	0.49
Love	172	3.10
Pride	70	1.26
Regret	40	0.72
Relaxed	25	0.45
Sadness	137	2.47
Shame	22	0.40
Surprise	83	1.49
Sympathy	31	0.56

Figure 2: Emotion categories Suet Yan and Turtle (2016)

Yet, as this model contains many categories, not all types of emotions were included for the annotation of the tweets about Donald J. Trump. These emotions were not included for a number of reasons. Firstly, because some emotions had already been included on the basis of the model of Ekman (‘anger’, ‘fear’, ‘happiness’, ‘sadness’ and ‘surprise’).

Secondly, some emotions were too closely related to emotions that were already in the list of possible emotions, which would have made the annotation too confusing and difficult. For example, ‘Amusement’ is closely related to ‘joy’. ‘Joy’ is less aroused than ‘amusement’. Yet, the boundary between the two would be too difficult to draw for this annotation. On the same basis, ‘boredom’, was excluded from this list in favour of ‘indifference’ and ‘fascination’ in favour of ‘admiration’. Accordingly, ‘pride’ and ‘sympathy’ were excluded in favour of ‘admiration’.

‘Desperation’ was excluded on the basis that this emotion would mostly include the emotions ‘sadness’ and ‘fear’. ‘Excitement’ was excluded because it is closely related to the combination of ‘joy’ and ‘surprise’. On top of that, ‘hate’ was excluded because it often involves ‘anger’ and ‘disgust’.

The categories that were least frequent (less than 0.50 %) in the tweets of Suet Yan & Turtle were also excluded as they would probably be very infrequent in our examples too ('confidence', 'curiosity', 'exhaustion', 'inspiration', 'longing', 'relaxed', 'shame' and 'jealousy'). However, 'indifference' was not excluded as the annotation of our test corpus showed that this emotion was more present in our corpus than in that of Suet Yan and Turtle (1.5 %) .In sum, from the 28 categories from Suet Yan & Turtle, 7 emotions were chosen for our annotation: 'admiration', 'doubt', 'gratitude', 'hope', 'love', 'regret' and 'indifference'.

The emotion 'conviction', viz. a strong belief or opinion about someone, was included, though not present in any of the emotion models, as our test corpus showed that this emotion was sometimes (in 2.4 % of the tweets) indicated as an alternative when the tweet could not be annotated on the basis of the emotions of Ekman.

3.4 Automatic emotion detection

On the basis of the annotated corpus a small machine learning system was built. The system was based on character bigrams that were inferred from the training data. Then, tenfold cross-validation was performed on the data with Support Vector Machine with a linear kernel. The tenfold cross-validation means that the initial corpus would be divided in 10 parts randomly. In the first fold the data would, for example, be split in 90 per cent training data and ten per cent test data. The percentage changes for every fold and eventually every tweet will be used as test and as training data at least once. Annotations were used as the gold standard, more specifically the annotations of the first emotion category. The second emotion category was not included in this system.

4.Results

4.1 Corpus analysis

in this section, we will detail some of the most important findings from our annotations of the tweets. In the first part, the analysis will only take into account the data separately. In the second part, there will be a comparison of, for example, emotion and sentiment on the basis of pivot tables that were made in Excel. The third part will divide the overall results into results per moment in the election. The last part is an overview of the lexicalisation of the emotions in this corpus.

4.1.1 Emotion presence

It can be seen from Figure 3 that the overall majority of tweets contain emotions. Only 10 out of 556 tweets or 2 per cent (see Table 1) are purely informative and do not convey any emotion. If a tweet was not clear on this part, it was decided to indicate the tweet with 'no emotion' (see Example 1) as it would have been too difficult to pinpoint the specific emotion when the annotator was not sure whether it really contained an emotion.

- (1) Tweet 393: During the primaries, #Trump usually lost the #vote of voters who were late deciders. The exit #polls suggest that he won late deciders. ('no emotion')
- (2) Tweet 385: Really tried to stay up until 270, but I keep falling asleep. I hope a miracle happens while I'm sleeping. #ImWithHer #NeverTrump (emotion: 'hope' and 'frustration')

4.1.2 Emotion categories

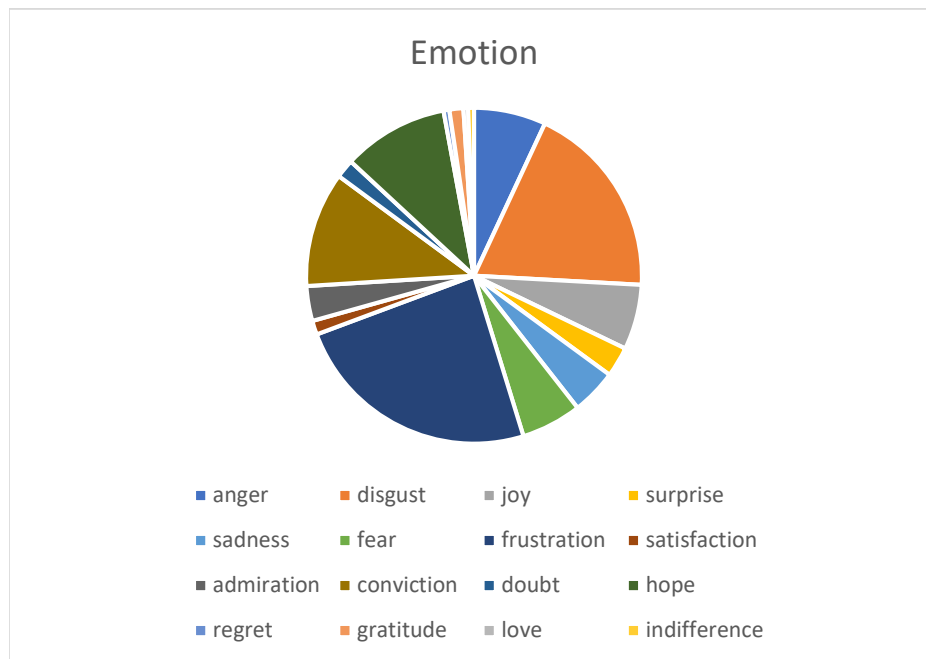

Figure 4: Emotion categories

Anger	62
Disgust	169
Joy	56
Surprise	26
Sadness	39
Fear	52
Frustration	215
Satisfaction	12
Admiration	30
Conviction	99
Doubt	16
Hope	91
Regret	5
Gratitude	12
Love	4
Indifference	5
Total	893

Table 2: Emotion categories

During the annotation, it was possible to indicate a second emotion for each tweet, which means that sometimes a tweet contained one emotion and sometimes two. In this section, only the combination of the first and the second emotion is mentioned, as both the first and the second emotion had a very similar division between the emotion categories. From Figure 4, it can be seen that most of the tweets conveyed the emotion ‘frustration’, accounting for 24 per cent of the instances. ‘Love’, ‘indifference’ and ‘regret’ are the least present in the combined emotion diagram, with less than 5 instances each, just a fraction out of the 893 instances.

‘Disgust’ is the second most conveyed emotion and accounts for 19 per cent of the total number of tweets and ‘conviction’ is the third most important, with 99 instances. ‘Joy’ and ‘fear’ are almost equally present in the corpus, respectively 56 and 52 times. ‘Surprise’ and ‘gratitude’ were not often conveyed and only account for respectively 3 and 1 per cent of the corpus. Twitter users were ‘sad’ in 39 of the 893 conveyed emotions, while they had ‘hope’ in almost 10 per cent of the cases. ‘Doubts’ were cast a total of 16 times and twitter users were ‘angry’ 62 times. They ‘admired’ someone or something 30 times or 3 per cent of the total emotions conveyed.

4.1.2.1 Division of the emotion models

This section will give an overview of which of the emotion models of Ekman (1992), Russel (1980) and Suet Yan and Turtle (2016) could have been used to annotate the most tweets in this corpus. Ekman's model consists of the following emotions: 'anger', 'sadness', 'joy', 'surprise', 'fear' and 'disgust' (see Examples 3,4,5,6,7 and 8). These emotions are amongst the emotions that are most used within the corpus. 'Disgust' is the second most frequently used emotion in the corpus. Yet, 'frustration', which was conveyed the most, is not present in the model of Ekman. Other emotions that were also often conveyed, such as 'hope' and 'conviction', are not present in this model either. In total 404 out of 893 emotions could have been annotated on the basis of the model of Ekman.

Not all emotions of Russel's circumplex model are used in this study. Only the four corners of the model: 'happy', 'sad', 'frustrated' and 'satisfied' (see Examples 5,7, 9 and 10) are used as emotions that could be annotated in the corpus. 'Happy', which refers to 'joy' in this corpus, accounts for 56 out of 893 instances. 'Sadness' and 'satisfaction' are only present 39 and 12 times respectively. However, this model includes 'frustration', which is the emotion that is most present in the corpus, accounting for 215 out of 893 cases. In total 322 out of a total of 893 emotions could have been annotated solely on the basis of the emotions that were extracted from the model of Russel in this study.

The emotions that we extracted for this corpus from the study of Suet Yan and Turtle (2016) are the following: 'anger', 'joy', 'surprise', 'sadness', 'fear', 'admiration', 'doubt', 'hope', 'regret', 'gratitude', 'love' and 'indifference' (see Examples 5, 6, 7, 8, 11, 13, 14, 15, 16, 17, 18). All of these emotions account for 394 out of 893 emotion instances. 'Hope', which is not present in the emotion models of Ekman and Russel, accounts for the largest number of emotion instances: 91. Ekman's emotions 'joy', 'sadness', 'surprise' and 'fear' are the emotions of Suet Yan and Turtle which are most present. Yet, the other emotions only account for a small number of the total corpus. 'Indifference', which also has a low frequency percentage in their study (0.43 per cent) , has a slightly higher percentage of 0.55 per cent in this corpus.

(3) Tweet 10: 'Anger' and 'frustration': @AnnCoulter you are a #failed author. Voting #trump loses interest. People look for quality books and not for degrading low iq gossip

(4) Tweet 33: 'Disgust' and 'anger': #Trump supporters are White Supremacists, Morons, Pedophiles, Anti Semites and #Racists, but even they know that BILLIONAIRES MUST PAY TAXES

(5) Tweet 418: 'Joy': #TrumpTrain #maga is already happening! Just heard an Ace Hardware commercial saying Merry Christmas! #boycottgrubhub

- (6) Tweet 82: 'Surprise' and 'disgust': As a former #debate pro, I'm blown away by #Trump's pivot from a Q about #sexualassault to...#ISIS. Clumsy, horrifying, loser-y. #misogyny
- (7) Tweet 105: 'Sadness' and 'frustration': It hurts my heart to see strong women defend Donald Trumps actions & words. It is a huge step backward for all of us. #Trump
- (8) Tweet 279: 'Fear': #Education is at stake #Equality is at stake #Health of our #Planet and #Children are at stake #BeforeTheFlood #imwithher #LoveTrumpsHate
- (9) Tweet 283: 'Frustration' and 'conviction': How much shit did I take for saying #NeverTrump was pure semitism? Then they nominate a TWO Jew ticket. Can't be coincidence. I was right.
- (10) Tweet 280: 'Satisfaction' and 'joy': @NewWorldNewAge already did and proudly voted for #Trump. Felt great!
- (11) Tweet 350: 'Admiration' and 'joy': So proud of all the hard work @realDonaldTrump has put in. He finally won!! #MakeAmericaGreatAgain
- (12) Tweet 384: 'Conviction' and 'satisfaction': #Trump makes the world a safer place....no war with Russia...and more help for unborn Americans. God willing! #ElectionNight
- (13) Tweet 416: 'Doubt' and 'frustration': #trump. Will even one of these protesters honour Veterans Day? Would even one of them?
- (14) Tweet 455: 'Hope' and 'disgust': @luhanWho keep making this country divided. Hope you and all the pc people finally realize they are hypocrites and shut the fuck up #trump
- (15) Tweet 78: 'Regret' (irony) and 'fear': Sorry, Donald #Trump, but you looked scary tonight. Frowning. Restlessly pacing around. Looking like a mad Mussolini. #Unpresidential.
- (16) Tweet 526: 'Gratitude': @KurtEichenwald THANK YOU SO MUCH FOR tweeting/posting the findings of your #Trump investigations published in @Newsweek!!!
- (17) Tweet 148: 'Love' and 'disgust': RT @caltanee: I love the way #Trump put checkmate on Anderson cooper & slap down hilary Clinton on lying about the emails.She got cornered like a rat
- (18) Tweet 311: 'Indifference' and 'disgust': @preueth|I don't care about Democrats OR Republicans. There's a lot of shit on both sides.|That's what drives the #Trump movement.

4.1.3 Sentiment

Figures 5 and 6 show that the division between negativity and positivity for both the first and the second emotion is fairly similar. In most of the tweets, the sentiment is negative, 59 per cent for the first emotion and 65 per cent for the second emotion (see Example 20). 1 in 5 tweets contain a positive sentiment (see Example 22). Only 3 per cent of the first emotion and 1 per cent of the second emotion are neutral (see Example 21). Extreme positivity or negativity was also seen in some cases. Very negative is most used in both emotions instances : 11 per cent for the first emotion and 7 per cent for the second emotion (see Example 19). Extreme positivity has an equal percentage of 6 per cent for the first and the second emotion (see Example 23).

(19) Tweet 429: 'Very negative' ('disgust'): RT @PhilipJoel: Im not crying cos #trump won. I'm crying cos Racism Won. Sexism Won. Homophobia Won. Hate Won. Money Won. Stupidity Won.

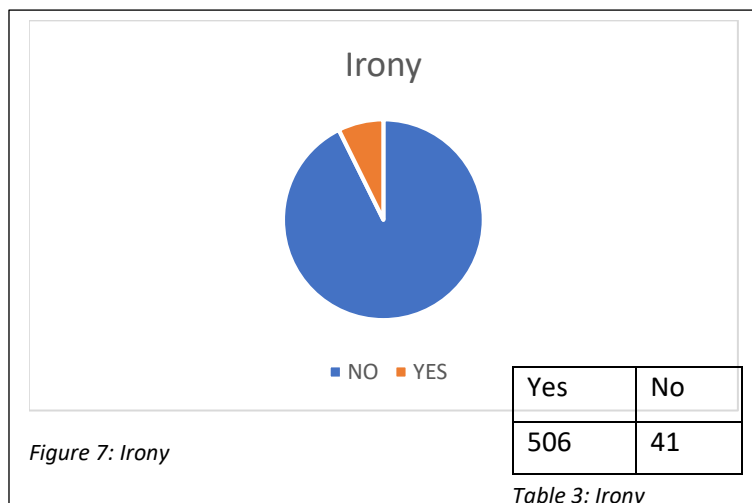

(20) Tweet 433: 'Negative' ('frustration' and 'anger'): Wow. The #Trump riots are still just a bunch of millennials trying to get internet famous. Get the fuck out of here.

(21) Tweet 102: 'Neutral' ('doubt' and 'conviction'): #debate Does @mike_pence have the courage and conviction of his religion to drop #Trump? He needs to do what is right for his country.

(22) Tweet 177: 'Positive' ('gratitude' and 'conviction'): @notTrumpfoPrez @HillaryClinton Thanks man. We got to stand together and defeat this thug revolution. #ImWithHer #NeverTrump

(23) Tweet 37: 'Very positive' (love and joy): #BOOM|I love my @FLOTUS and I love when she speaks truth to #Trump!!!

4.1.4 Irony

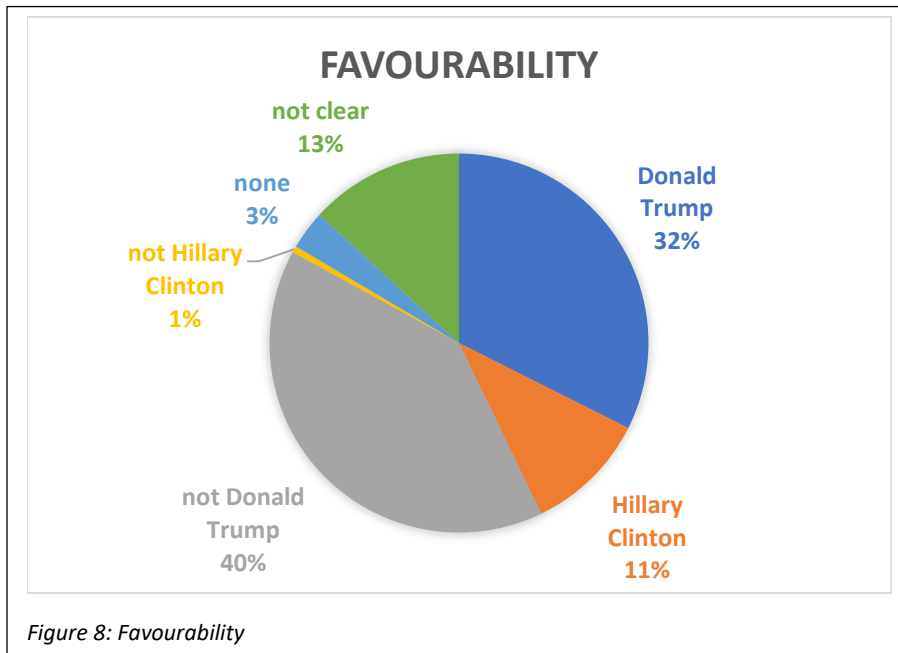

If a tweet contained an emotion, the annotator also had to indicate whether the tweet was ironic or not. Out of 546 tweets that contain an emotion, 40 tweets also contain irony, which accounts for 7 per cent of the corpus. In Example 24 the part where the tweet author says “Guess he wasn’t strong enough’ is ironic. Example 25 shows a tweet author who writes that Donald Trump is a “lovable oaf” but he or she does not seem to mean it. This becomes clear by “(insert heavy sarcasm)”.

(24) Tweet 50: I knew a young #USMC vet who suffered from #PTSD & addiction. He took his life yesterday. Guess he wasn't strong enough. Go to hell #Trump.

(25) Tweet 83: Oh the debates 'sigh' I love the African Americans... oh and the Latinos and the Hispanics. #Trump is such a lovable oaf (insert heavy sarcasm)

4.1.5 Favourability

Donald Trump	177
Hillary Clinton	57
Not Donald Trump	219
Not Hillary Clinton	3
None	18
Not clear	72
Total	546

Table 4: Favourability

If a tweet contained an emotion, the annotator also had to indicate which presidential candidate the author of the tweet was most likely to vote for. Mostly, the favour for a particular candidate would be clear due to certain hashtags, such as ‘#ImWithHim’, ‘#ImWithHer’, ‘#MAGA’, ‘#MakeAmericaGreatAgain’, ‘#TrumpTrain’ and so on (see Examples 26-30). Sometimes a tweet did not exactly contain words or hashtags that indicated that they would like to vote for someone, but indicated whom they definitely did not like by for example ‘#LockHerUp’ or ‘#NeverTrump’. In some cases the tweet was not clear about the preferred candidate. Then the tweet was annotated with ‘not clear’. If a tweet contained anger towards both candidates, this was indicated with ‘none’.

This corpus not only contains tweets from American citizens, but also tweets that were posted all around the world. Consequently, this method could not be used to predict the outcome of the American elections. Nevertheless, it can indicate the popularity or non-popularity of a particular presidential candidate.

Figure 8 and Table 4 indicate that most of the tweets (40 % or 177 out of 546 tweets) are against Donald Trump (see Example 29). Yet, surprisingly, the number of Twitter users that are in favour of Donald Trump is 32 per cent of the tweets (see Example 26). This means that the majority of Twitter users are either in favour of Donald Trump or against him. The number of tweets that contain elements in favour of Hillary Clinton is much lower: 11 per cent (see Example 27) , while only one per cent of tweets are against Hillary Clinton (see Example 29). In 7 out of 546 tweets (13 %) the author was not clear about his or her favourability for a particular candidate.

Only 3 per cent of the Twitter users in the corpus indicated in their tweets that they were not in favour of both candidates (see Example 30).

(26) Tweet 9: 'Donald Trump': Saw a girl wearing a #MakeAmericaGreatAgain hat on my way to class. At least she has some brains!

(27) Tweet 12: 'Hillary Clinton': :#obamatownhall Watching @POTUS makes it obvious how incredibly unfit #Trump is. There is only one sane choice #ImWithHer #NeverTrump

(28) Tweet 16: 'Not Donald Trump': swoozyqyah his refusal to pay taxes is a big screw u to all of us|His gifts are chump change for a true millionaire. #NeverTrump

(29) Tweet 353: 'Not Hillary Clinton': Are #NeverTrump folks ready to become never Clinton voters yet?

(30) Tweet 266: 'None': @bodysculptorokc Ya know ...I'm #NeverTrump #NeverHillary ||Nice to know ya though.

4.1.6 Pivot tables

4.1.6.1 Sentiment and emotion

Figure 8: Pivot table sentiment and emotion

	Negative	Neutral	Positive	Very negative	Very positive	Total
Admiration			11		8	19
Anger	17			13		30
Conviction	27	5	34	1	4	71
Disgust	74			18		92
Doubt	5	5				10
Fear	24			9		33
Frustration	128			8		136
Gratitude			3		4	7
Hope	11	1	40		2	54
Indifference	1	3				4
Joy			20		11	31
Love	1		2		1	4
Regret	2					2
Sadness	18			10		28
Satisfaction			6			6
Surprise	13	1	2	2	1	19
Total	321	15	118	61	31	546

Table 5: Pivot table sentiment and emotion

Table 5 mentions the number of tweets that are used for each first emotion combined with the sentiment. Figure 8 represents the same data. 'Frustration' was conveyed the most number of times, and mostly the sentiment it conveyed was negative. A very negative sentiment is only found in 8 out of 136 cases. With the emotion 'admiration', the number of positive and very positive instances is more balanced, 11 times positive and 8 times very positive.

'Anger' was conveyed 17 times in a negative way and 13 times in a very negative way. 'Conviction', i.e. a strong belief or opinion about someone, has a more complicated pivot table, as it was conveyed for all types of sentiment, except for neutrality. The sentiment is more or less balanced between (extreme) positivity and (extreme) negativity. 'Disgust', which was also one of the emotions with a large number of occurrences, is indicated more as negative than as very negative (74 versus 18 times). 'Doubt' is equally balanced between negativity and neutrality. 'Fear' is in 9 times out of 24 issued as very negative.

'Gratitude' does not have a high number of occurrences, but the number is almost equally balanced between positivity and extreme positivity. The occurrence of 'hope' is divided between three sentiment types. The emotion is most present as a positive sentiment and 11 times as a negative sentiment, which means that the author did not have much hope. Once, it was conveyed as a neutral sentiment.

'Indifference' was one time conveyed as a negative sentiment, but other times it has a neutral connotation. Slightly more than 1 in 2 indications of the emotion 'joy' are very positive. 'Love' was one time conveyed as a negative sentiment, the other times the sentiment is either positive or very positive. 'Regret' is only found with a negative sentiment. In 1 out of 3 times, the sentiment of the emotion 'sadness' was conveyed in a very negative manner. 'Satisfaction' is only indicated as positive. 'Surprise' also has a more complicated pivot table, as the emotion is mostly indicated with a negative sentiment. Once, 'surprise' is neutral and positivity and extreme negativity are both indicated 2 times. There is also one case of extreme positivity together with 'surprise'.

Generally, these figures show that negativity is mostly related with negative emotions, such as 'frustration', 'disgust', 'anger', etc. The opposite is also true as positive emotions (e.g. 'joy', 'love') are mostly found with a positive sentiment. Some emotions have a more complicated pattern, such as 'conviction' or 'surprise'.

4.1.6.2 Emotion and Irony

4.1.6.2.1 Emotion 1 and irony

	No	Yes	Total
Admiration	19		19
Anger	29	1	30
Conviction	67	4	71
Disgust	82	10	92
Doubt	9	1	10
Fear	32	1	33
Frustration	124	12	136
Gratitude	7		7
Hope	51	3	54
Indifference	3	1	4
Joy	30	1	31
Love	3	1	4
Regret	2		2
Sadness	25	3	28
Satisfaction	6		6
Surprise	17	2	19
Total	506	40	546

Table 6: First emotion and irony

Table 6 gives an overview of the number of times irony is indicated and which emotion the ironic tweet conveyed. Irony is found the most times together with the emotion 'frustration'. In addition, 'disgust' also has a high number of ironic tweets (1 in 4 of the total number of ironic tweets). The other emotions are less frequently used together with an ironic statement. Some emotions, such as 'admiration', 'gratitude', 'regret' and 'satisfaction', do not occur in an ironic sentence or tweet.

4.1.6.2.2 Emotion 2 and irony

	No	Yes	Total
Admiration	11		11
Anger	29	3	32
Conviction	26	2	28
Disgust	72	5	77
Doubt	5	1	6
Fear	18	1	19
Frustration	73	6	79
Gratitude	3	2	5
Hope	37		37
Indifference	1		1
Joy	17	8	25
Love			
Regret	2	1	3
Sadness	10	1	11
Satisfaction	6		6
Surprise	7		7
Total	318	29	347

Table 7: Second emotion and irony

Table 7 gives an overview of the number of times irony is indicated and which type of emotion the second emotion is. The outcome is slightly different than that of the previous table. This time not 'frustration', but 'joy', is the emotion that conveyed the most irony. This means that the sentences made it look like they conveyed 'joy', but they in fact meant the opposite with their tweet. 'Frustration' is here the second most used emotion with irony and 'disgust' the third most emotion. Other emotions are less frequently combined with irony. Here too, 'admiration', 'regret' and 'satisfaction' are not found with an indication of irony. On top of that, 'hope', 'indifference' and 'surprise' are also not linked with irony in this case.

4.1.6.3 Emotion and implicit

4.1.6.3.1 Emotion 1 and implicit

	No	Yes	Total
Admiration	19		19
Anger	30		30
Conviction	71		71
Disgust	92		92
Doubt	10		10
Fear	33		33
Frustration	135	1	136
Gratitude	7		7
Hope	54		54
Indifference	4		4
Joy	31		31
Love	4		4
Regret	2		2
Sadness	28		28
Satisfaction	6		6
Surprise	18	1	19
Total	544	2	546

Table 8: Implicit first emotion

Table 8 shows that only two times the first emotion is indicated as implicit. This is the case with ‘frustration’ and ‘surprise’. The reason why the first emotion is only once indicated as implicit is probably because the first emotion the annotator sees is often the most explicitly mentioned in the tweet.

4.1.6.3.2 Emotion 2 and implicit

	No	Yes	Total
Admiration	10	1	11
Anger	28	4	32
Conviction	28		28
Disgust	77		77
Doubt	6		6
Fear	18	1	19
Frustration	71	8	79
Gratitude	5		5
Hope	34	5	39
Indifference	1		1
Joy	24	1	25
Regret	3		3
Sadness	5	6	11
Satisfaction	6		6
Surprise	7		7
Total	323	24	347

Table 9: Implicit second emotion

As the second emotion that is indicated is usually also the second emotion that the annotator perceives, they are often more implicit (see Table 9). The emotion which has the most implicit instances in this corpus is ‘frustration’, with 8 out of 24 total implicit indications. ‘Sadness’ was 6 times perceived implicitly. With the emotion ‘hope’, five tweets have been indicated as implicit. ‘Joy’ and ‘fear’ were left implicit both one time.

4.1.6.4 Emotion and target

4.1.6.4.1 Emotion 1 and target

	Clinton	Trump	Total
Admiration	3	8	11
Anger	3	14	17
Conviction	3	29	32
Disgust	14	45	59
Doubt		4	4
Fear	1	20	21
Frustration	9	47	56
Gratitude	1	1	2
Hope	13	28	41
Joy	4	16	20
Love		2	2
Regret		2	2
Sadness		11	11
Satisfaction	2	2	4
Surprise		11	11
Total	53	240	293

Table 10: Target First emotion (Trump vs. Clinton)

Table 10 gives an overview of the target that a particular emotion is referred to. In the corpus, there are many targets, that often only occurred once. Therefore, this table only compares the times an emotion was referred to either presidential candidate, i.e. Trump or Clinton.

It can be seen that many more emotions are referred to Trump (240 vs. 53 for Clinton). This can be explained due to the fact that the initial hashtags to retrieve tweets mostly contained Trump and did not necessarily refer to Clinton. On top of that, this research would like to give an overview of the reputation of Donald Trump and not of Hillary Clinton.

As 'frustration' and 'disgust' are the most used emotions in the overall corpus, they are also the most used emotions to target Donald Trump. 'Conviction', which can be either (very) negative, (very) positive or neutral, is the third most conveyed emotion in reference to Trump. 'Hope' is also often present and may refer to the 'hope' of him being elected President. The emotion 'fear' was 20 times used with Trump as a target. Nevertheless, other emotions were less frequently used to refer to him. 'Gratitude' was only used once to target Donald Trump and once to target Hillary Clinton.

The emotion which was most used with Clinton as a target is that of 'disgust'. The second most used emotion with her as the target is that of 'hope'. In this case, this may often represent the 'hope' of her becoming President. 'Frustration' is the third most used emotion with 20 out of a total of 53 targets. 'Admiration', 'anger', 'conviction', 'fear', 'gratitude', 'joy' and 'satisfaction' are only present a few times in the entire corpus with Hillary Clinton as target (less than 5 times). The emotions 'doubt', 'love', 'regret', 'sadness', 'satisfaction' and 'surprise' are not found as a first emotion with Clinton as target.

4.1.6.4.2 Emotion 2 and target

	Clinton	Trump	Total
Admiration		4	4
Anger	2	9	11
Conviction	3	10	13
Disgust	16	35	51
Doubt		4	4
Fear	3	8	11
Frustration	6	27	33
Gratitude		2	2
Hope	3	17	20
Joy	4	12	16
Regret	1	1	2
Sadness		5	5
Satisfaction	1	3	4
Surprise		2	2
Total	39	139	178

Table 11: target second emotion (Trump vs Clinton)

In Table 11, Donald Trump is also the target which was mentioned the most, compared to Hillary Clinton. Again, the reason for this is because the tweets were retrieved with hashtags that mentioned Donald Trump or had something to do with the presidential candidate.

Contrary to the previous table, 'disgust' is now the emotion which was most referred to Trump, while 'frustration' is the second most found for the second emotion. 'Disgust' is also the most used emotion to target Hillary Clinton.

All other emotion targets about Hillary Clinton are much less present (less than 4 times). Some emotions are not even present in the corpus with her as a target ('admiration', 'doubt', 'gratitude', 'sadness' and 'surprise'). This means that 'admiration', 'doubt', 'sadness' and 'surprise' are never used to refer to her, as they are also not present in the Table 10. 'Hope', 'conviction' and 'joy' are also quite frequently used to target Donald Trump. 'Fear' is only used in 8 out of a total of 139 times and 'anger' 9 times. Other emotions are even less frequent (less than 6 times). Contrary to Hillary Clinton, Trump is used as a target for each emotion category at least once.

4.1.7 Moments

4.1.7.1 Emotions

	Moment 1	Moment 2	Moment 3	Moment 4	Moment5	Moment6	Moment 7
Anger	12.6 %	6.9%	6.8%	2.3%	5.4%	8.9%	5%
Disgust	26%	24.6%	21.2%	20.1%	10%	13.8%	15%
Joy	7.6%	4.6%	3.8%	6.1%	15.4%	4.8%	0.8%
Surprise	1.7%	4.6%	0.7%	1.5%	6.9%	1.4%	3.3%
Sadness	1.7%	3.8%	2.3%	3%	12.3%	4.8%	1.6%

Total	119	130	132	132	130	132	120

Table 12: Emotion presence throughout the moments

Table 12 gives an overview of which emotions were used during which important moment in the American elections. Given that not every moment has an equal amount of second emotion occurrences (see 'Total'), the total number of emotions varies through the moments. Therefore, it was decided to only display the percentages in the table. The cells indicated in yellow are the highest percentages of each emotion.

It can be seen that generally, 'disgust' and 'frustration' are the most frequently used emotions during each of the moments. During the first moment, the days before the second presidential debate, it is 'disgust' that is the most prevalent emotion, immediately followed by 'frustration' with only 0.8 per cent less instances. The second moment gives tweets that occurred the morning of the second presidential debate and after the leaking of the tapes of Trump. During that moment, both 'frustration' and 'disgust' were conveyed an equal number of times. With the third moment, the morning of the third presidential debate, the number of occurrences of 'frustration' sees a small increase, while that of 'disgust' decreases slightly. The fourth moment, the days after the announcement of the FBI investigation into Clinton's e-mails, the percentage of occurrences of 'frustration' drops from 28 per cent to 21.1 %. Later, during the fifth moment, the morning of the elections, the number of 'disgust' is halved and only covers 10 per cent out of 130 instances. Yet, the number of 'frustration' does not

change a lot (from 21.1 to 22.2 per cent). When the election result is announced (moment 6), the number of occurrences of 'frustration' and 'disgust' sees an increase. The seventh moment is during the protests that erupted after the election result was announced. The total number of emotions is much lower than for the previous moments, but the decrease in 'frustration' is still relevant (from 26.2 per cent during moment 6 to 18.3 % during moment 7).

Besides 'disgust' and 'frustration', there are also other emotions present during the seven moments. Some of these emotions show a pattern that fluctuates throughout the moments. 'Anger', for example, covers 12.6 per cent of the emotions during the first moment, but drops to 6.9 per cent on the morning before the third presidential debate. Another strong decrease is seen in the fourth moment, when it only reaches 2.3 percent. The percentage of 'anger' rises to almost 9 per cent during the sixth moment, after which it drops to 5 per cent.

The pattern of the emotion 'joy' also fluctuates. It starts at 7.6 per cent in the days before the second presidential debate. Afterwards, there is a slight decline in the second and the third moment and a slight increase in the fourth moment. The morning of the elections, there is a strong increase of 9.3 per cent and a drop to 4.8 per cent after the election result is announced. During the protests after the presidential election, 'joy' only covers 0.8 per cent of the emotions.

'Surprise', does not have a high number of instances throughout the moments. However, on the morning of the second presidential debate (moment 2) and the morning of the presidential election (moment 5) the percentage of 'surprise' is at its highest.

'Sadness' covers in most moment categories only a small percentage of the total emotions. Yet, during the fifth moment, there is a strong increase of 'sadness' in the tweets (to 12.3 %).

'Fear' covers a small percentage of the emotions during the first and the second moment. During the third moment, 'fear' is doubled to 6.1 per cent, and remains more or less the same. After the announcement of Donald Trump's victory, 'fear' drops to 3.4 per cent. During the last moment, which is the protests after the presidential election, 'fear' reaches its highest percentage 11.7 per cent or 14 instances on a total of 120.

The other two emotions that fluctuate throughout the moments are 'conviction' and 'hope'. 'Conviction' has only 5.9 per cent of instances in the first moment but eventually reaches 16 per cent in moment 4. Afterwards, its percentage drops radically to only 1.5 per cent in moment 5 and peaks at 20 per cent after the announcement of the outcome of the elections.

'Hope' shows a slight increase until the fourth moment after which it decreases again. During the protests, which is the seventh important moment, 'hope' reaches its highest occurrence of 20 per cent.

The other emotions only cover a small percentage of the instances in the corpus. ‘Satisfaction’, ‘regret’, ‘gratitude’, ‘love’ and ‘indifference’ never reach more than three per cent. ‘Admiration’ is at its highest during the fourth moment. Sometimes, ‘doubt’ does not occur during a particular moment (i.e. moment 1 and 3). The highest percentage of ‘doubt’ is reached during the sixth moment, when the outcome of the elections is announced (4.1%).

4.1.7.2 Favourability

	Moment 1	Moment 2	Moment 3	Moment 4	Moment 5	Moment 6	Moment 7
Donald Trump	31.6%	22%	35%	33%	41.2%	26.6%	37%
Not Donald Trump	44.7%	46.4%	38.8%	35.4%	46.2%	36.7%	30.1%
Hillary Clinton	9.2%	9.8%	10%	17.7%	2.5%	7.6%	20.5%
Not Hillary Clinton	0%	0%	0%	2.5%	0%	1.3%	0%
None	1.3%	7.3%	3.8%	6.3%	1.3%	1.3%	1.4%
Not clear	13.2%	14.6%	12.5%	5.1%	8.8%	26.6%	11%
Total	76	82	80	79	80	79	73

Table 13: Favourability throughout the moments

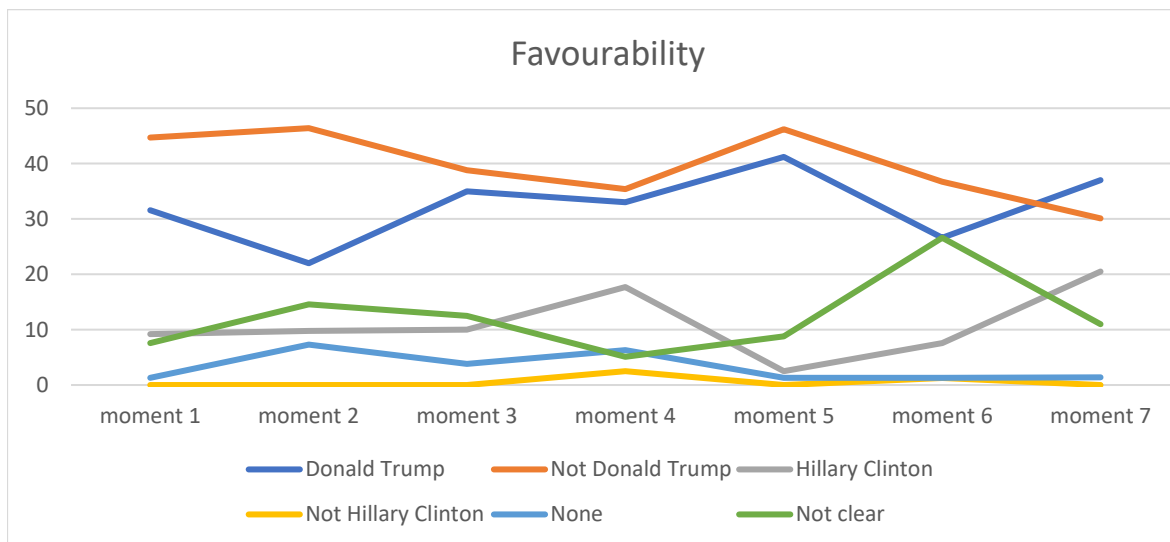

Figure 9: Favourability throughout the moments

Table 13 and Figure 9 give an overview of the annotations of 'in favour of' for each of the seven moments. 'Not Donald Trump' is always the most prevalent, except for the last moment. During the protests after the elections, most of the tweet authors used words or phrases that indicated that they were most in favour of 'Donald Trump'. Overall, 'Donald Trump' is the second most indicated option. Nevertheless, the percentage of these indications fluctuates and is at its lowest after the release of the tapes (moment 2) and at its highest on the morning of the presidential election.

The number of tweets that indicated 'Hillary Clinton' as their most favoured candidate is much lower than that of 'Donald Trump'. Contradictorily, it reaches the highest percentage for moment 4, when the FBI investigation into her e-mails was announced. The lowest percentage is seen on the morning of the presidential election, where 'Donald Trump' sees his highest percentage. While there is a high number of people that are 'against Donald Trump', the number of people that are 'against Hillary Clinton' is not as high.

For many moments, there are no instances that were annotated as 'not Hillary Clinton'. The highest number of tweets 'against Clinton' were found in moment 4, which is also the moment when her popularity was at its highest. For each of the moments, there are also a few tweet authors that claimed that they would not vote for either candidate. This number remains considerably low and is at its highest on the morning of the second debate. Sometimes, tweet authors were 'not clear' about their favour for or against any particular candidate. This number is at its highest during the first moment.

4.1.7.3 Sentiment

	Moment 1	Moment 2	Moment 3	Moment 4	Moment 5	Moment 6	Moment 7
Very negative	9.2%	11.5%	5.3%	12.1%	10.1%	9.8%	10%
Negative	65.5%	67.7%	69.7%	55.3%	60%	63%	53.3%
Neutral	2.5%	1.5%	2.3%	1.5%	1.5%	3%	0%
Positive	16.8%	15.4%	19%	27.2%	24.6%	19.7%	28.3%
Very positive	5.9%	3.8%	3.8%	3.8%	3.1%	4.5%	8.3%
Total	119	130	132	132	130	132	120

Table 14: Sentiment throughout the emotions

Figure 14 provides a clear overview of the sentiment for each of the seven moments during the American elections. From the overall charts that are described above, it could already be seen that the negative sentiment is the most prevalent. In fact, negativity scores the highest among each of the seven moments. The percentage remains quite stable but drops to 53.3 per cent during the protests (moment 7). Positivity is for all of the moments the second most prevalent option. Yet, its percentage increases from the first to the seventh moment. This sentiment is at its highest during the fourth moment and the protests (moment 7) when negativity was at its lowest.

Extreme negativity is more present than extreme positivity. The percentage of extreme negativity is quite stable but reaches its lowest point during the third moment. Extreme positivity was most indicated during the protests of moment 7.

Neutrality is not much present in the corpus, the percentage remains quite stable throughout the moments.

4.1.8 Lexicalisation

With the words that were indicated as emotions words or phrases in the corpus, an emotion lexicon was built. This section gives an overview of the most important findings in how the emotions were lexicalised.

The overall analysis (section 4.1.6.3) already gave an overview of which emotions were left implicit. Overall, we can see that not many emotions were implicit or at least indicated as implicit by the annotator. For the first emotion, this was only one time the case with 'frustration' and 'surprise'. The second emotion was more often perceived as implicit. Here, the two emotions that were most left implicit were 'frustration' (8 times) and 'sadness' (6 times).

What will follow is an enumeration of the 16 emotions that were used for this master's thesis, together with the most important findings on the lexicalisation of these emotions.

'Anger'

The words that are often indicated as belonging to the emotion anger are often capitalised (e.g. NO WAY.; NEVER NEVER EVER BE PRESIDENT; LIED AGAIN, ...). There is also a large presence of swear words, such as "shit", "F*CKING", "crap", "#Fucktard", "BS" (bullshit). Sometimes words are not spelled correctly as in "idjit" for "idiot" or "IM SIC OF" for "I'm sick of". This may have been done so deliberately or unconsciously.

'Disgust'

This corpus was obtained with tweets about Donald Trump and sometimes Hillary Clinton which means that these tweets are often political. The 'disgust' in these political tweets can be found through words such as "lying", "fraud", "corruption" and "hypocrite", which are often present in this corpus. Words such as "sexual assault", "misogyny", "sexist", "fascist", "homophobe" and "racist" are often found with Donald Trump as a target referring to his somewhat controversial declarations during his campaign and the leaked tapes. Tweet authors also use words to refer to Hillary Clinton, the most recurring combination in that case is that of "Crooked Hillary". "Rigged", a word which Donald Trump often used during his speeches to refer to the upcoming elections, is adopted by the Twitter users in this corpus. Other words that do not necessarily refer to Donald Trump or Hillary Clinton but do convey the emotion 'disgust' are for example: "nauseating" and "hideous".

'Joy'

As was also the case with 'anger', 'joy' is sometimes seen in words that are capitalised, as in "#VICTORY" and "#TRUMPWON". This then results in a sentiment that is indicated as 'very positive'. Words such as awesome, happy, glad and amazing are also found in the corpus. In addition "truths" was indicated as conveying this emotion. Yet, 'joy', is not always found in combination with words that generally have a positive connotation. Sometimes, sentences or phrases which contain negative words also convey a positive emotion such as in "Some SWAMP is starting to self-destruct (sic.) or implode by itself". In this case, the author is joyful that this is happening although the words "SWAMP" and "self-destruct" (sic.) are negative words. Elements that contain 'joy' are not always words that can be found in the dictionary, sometimes exclamations (e.g. "Whoo hoo!") are used or smileys, such as ":D".

'Surprise'

The emotion 'surprise' was most conveyed on Election day and when the victory of Donald Trump became imminent. Words that convey this emotion are for example: "blown away", "mind boggling", "shocked", "aghast" and "baffled". Also for this emotion exclamations such as "Wow." were found. Tweet authors who are 'surprised' often use phrases or short sentences to convey their emotions (e.g. "Is this for real" and "what alternate universe did I walk into?").

'Sadness'

In the annotation guidelines the difference between 'sadness' and 'fear' was indicated as 'sadness' being about the present and 'fear' about the future. When the election result was announced, a tweet author referred to the result as "Brexit ii", which was indicated as a word that conveyed 'sadness'. However, to know this, one needs a broad general knowledge. The negative reaction on the election result is also seen in words as "Racism won" or "Sexism won". In addition, tweets contain 'sad' words such as "hopelessness", "depressed", "sadly" and "depressing". The emotion is also conveyed with phrases or (short) sentences. (e.g. "Lost the ability to prioritize and think logically" or "We only have one spaceship earth"). Also in this case, sometimes a smiley was used as in "Unkind things :(".

'Fear'

The emotion 'fear' is most conveyed during the protests that erupted after the announcement of the election result. 'Fear' is sometimes targeted towards Donald Trump with for example "#TRUMP=HITLER" or "Mad Mussolini". Swearwords are in this case also used (e.g. "Were fucked"(sic). People were worried about the future of the world and of America which becomes clear from phrases such as "#Education is at stake", "The world is doomed" or "He's getting the nuclear codes". The last sentence does not have a negative word but with world knowledge the sentence in itself can be

indicated as containing 'fear'. Words that are also sometimes used in combination with the emotion 'fear' were "scary" and "fear" itself.

'Frustration'

'Frustration' is the most conveyed emotion throughout this corpus. The lexicon that was made of this corpus reveals that often longer phrases or sentences indicate this emotion. For example: "#Trump is acting like a toddler" or "He has only 30 words in his vocabulary". In the previous sentences the tweet author is 'frustrated' about Donald Trump's behaviour and word usage. 'Frustration' is also targeted at the media, which is for example the case in 'Unfit for providing news'. "Unfit" is also a word that was often seen in word combinations or phrases that conveyed 'frustration'. In addition, sometimes words are written badly, as in "Fek off" for "Fuck off". 'Frustration' is also felt in phrases such as "brain-dead", "Does everyone realise", "Come on now!" and "So say it". The emotion itself was also found literally in the corpus.

'Satisfaction'

'Satisfaction' was one of the fewer present emotions in this corpus. The phrase "Finally gets a taste of their own medicine" was found to convey this emotion as this person is 'satisfied' that this has finally happened. In "#AmericaisAlreadyGreat" the tweet author is satisfied about America. "HAHAHAHAHA" conveys how someone was 'satisfied' when Donald Trump called Hillary ineffective. Other phrases that indicated 'satisfaction' were "History is within our reach" and "Felt Great!".

'Admiration'

In some cases tweet authors admired someone which they mostly conveyed through short phrases or words. A word that often recurs in various forms is "Congrats" or "Congratulations". "God Bless America" was also indicated as 'admiration'. Also for this emotion sometimes words are capitalised which made them 'very positive'. This was the case for "AWESOME AWESOME job" and "STANDING OVATION". Admiration for a particular person became also clear through words such as "brains"; "proud", "RIP", "#respect" and "American hero".

'Conviction'

The emotion 'conviction' is one of the emotions that was often present in this corpus. It was seen that many modals were indicated as conveying this emotion. Examples include "you must have discipline", "ppl should force", "should have to vote", "we need a strong president". In addition words of 'conviction' were also "dislike", "think", "disagree" or "it seems to me". Sometimes this emotion is conveyed with capital letters as is the case for "EVERY VOTE COUNTS" or "I do NOT support".

'Doubt'

In comparison to 'frustration' or 'conviction', 'doubt' is not often present in this corpus. However, every mentioning of 'doubt' was more or less explicitly found in the tweets. Sometimes this was seen in (small) sentences such as "are #NeverTrump folks ready to become never Clinton voters yet?", in which the tweet author is doubting whether Clinton voters would change vote or not. "If" was in this corpus also an indication of 'doubt', together with "maybe". The modals "would" and "will" were also found to convey 'doubt'. The next phrases were also indicators of 'doubt': "Right?", "Fair?" and "wonder how".

'Hope'

'Hope' was conveyed a large number of times throughout this corpus. In total only 5 times 'hope' was left implicit. Many times words such as "please" "praying" and "Dear Lord" are used to convey this emotion. "Matter of time" or "Fingers crossed" were also used in this corpus. In "#Trump will lose his mind & go on a AM Twitter Tirade" the 'hope' is that something will happen and the reader will need world knowledge to understand. Many times 'hope' was also found in tweets where people wanted to encourage others to vote (e.g. "Get out and vote"). "I hope" was also literally present in this corpus.

'Regret'

'Regret' was in total conveyed five times explicitly in this corpus. No sentences with an implicit 'regret' are found. The first word combination that is used in combination with 'regret' is 'I can't' which means that a person 'regrets' not being able to do something. The second indication of 'regret' is in the following sentence: "I've had more focused, intelligent, and less rambling conversations with my 4 year old niece." In this sentence a person 'regrets' having watched the presidential debate. Also "sorry" and "I regret" were found to convey the emotion regret in this corpus.

'Gratitude'

The emotion 'gratitude' was in total conveyed 12 times explicitly in this corpus. "Thank you" or "Thanks" or other forms of the verb "to thank" are the most used. Sometimes the verb is put into capitalised letters as in "THANKS" or "THANK YOU SO MUCH". This emotion was then indicated with a very positive sentiment. 'Gratitude' was also conveyed with "grateful".

'Love'

'Love' is mentioned five times explicitly in this corpus. The words that are used to refer to this emotion are somewhat obvious. Three times the emotion was conveyed with "love", the other times it was conveyed with "loving" and "love the way". "The way" was not deleted in the latter instance as "love the way..." is an often heard collocation.

'Indifference'

'Indifference' is an emotion that has a very low presence in this corpus. In total, only 3 emotion instances of 'indifference' were explicit in the tweets. The first phrase which conveys 'indifference' is "nothing shocks me anymore". "Don't care" is the second word combination that was found to clearly convey indifference. The last one is a small sentence: "This isn't a political tweet". In this tweet someone is saying that he or she is leaving the United States, but adds that it is not a political tweet. In that sense, he or she was 'indifferent' to the American elections.

The description of the emotion lexicalisation show some recurring findings. Sometimes, words are capitalised, which gives the emotion a stronger effect. This was the case with 'gratitude', 'admiration', 'fear', 'joy' and 'anger'. For some of the tweets, general knowledge is necessary to determine its emotion(s). With a few emotions, determining the category was easier as the emotion was explicitly mentioned in the tweet (e.g. "love"). Nevertheless, if words are not spelled correctly (e.g. "idjit") or abbreviated (e.g. "BS") this may make the annotation process more difficult.

4.2 Automatic emotion detection

4.2.1 Precision, recall and F-score

Emotion	Number	Precision	Recall	F-score
Fear	33	20.0	12.1	15.1
Frustration	136	28.8	44.9	35.1
Admiration	19	9.1	5.3	6.7
Conviction	71	18.1	21.1	19.5
Sadness	28	22.2	14.3	17.4
Joy	31	11.5	9.7	10.5
Anger	30	0.0	0.0	0.0
Regret	2	0.0	0.0	0.0
Hope	54	29.3	22.2	25.3
Disgust	92	31.3	39.1	34.8
Indifference	4	0.0	0.0	0.0
Surprise	19	0.0	0.0	0.0
Satisfaction	6	0.0	0.0	0.0
Doubt	10	0.0	0.0	0.0
Love	4	0.0	0.0	0.0
Gratitude	7	0.0	0.0	0.0

Table 15: Scores machine-learning system

Recall formula: $\frac{tp}{tp+fn}$

tp= true positive

fp= false negative

Precision formula: $\frac{tp}{tp+fp}$

tp= true positive

fp= false positive

F-score: $2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}}$

Table 15 shows the results of precision, recall and F-scores of the machine-learning system of the first emotion that was set up for this master's thesis. The precision formula is composed of the number of correctly predicted emotions of, for example 'frustration', divided through the total number of times 'frustration' has been predicted as an emotion. For precision, the scores tend to be higher when the emotion has a high number of occurrences (e.g. 'frustration' or 'disgust'). The opposite is also true as emotions that do not have a high number of occurrences, such as 'joy' or 'fear', have a lower precision score or a score that equals zero. The latter is the case for 'anger', 'regret', 'indifference', 'surprise', 'satisfaction', 'doubt', 'love' and 'gratitude'.

The table also shows some other differences between or difficulties with a few emotions. Although 'surprise' and 'admiration' have the exact same number of occurrences (19), 'surprise' has no precision score, while 'admiration' has a score of 9.1. Also for 'anger' there is no precision score, while 'joy', with only one occurrence more (31), has a score of 11.5. 'Hope' occurs 38 times less than 'disgust' but the precision score of the two emotions is almost equal (respectively 29.3 and 31.3). Although 'frustration' has the highest number of instances, it does not have the highest precision score, which is that of 'disgust'. It seems that 'joy' is more difficult to detect for the system than 'sadness'. The latter has less occurrences but an almost doubled precision rate (11.5 versus 22.2). Similarly, 'conviction' has a larger number of instances than 'hope', but a much lower precision rate (29.3 versus 18.1).

The table also indicates the recall of the emotions which in this case equals to the number of correctly predicted emotions, of for example 'frustration', divided through the total number of that particular emotion in the corpus (136 for frustration). The recall of 'frustration' is high compared to that of 'fear' (44.9 versus 12.1), while the difference in precision between them was not as large (28.8 versus 20.0). Similarly, the recall of 'admiration' is much lower than that of 'joy' (5.3 versus 9.7), although their precision rates do not differ as much (9.1 versus 11.5).

Also 'hope' and 'frustration' have an almost equal precision rate (29.3 versus 28.8) while their difference in recall is much larger (22.2 versus 44.9). The table also shows the F-scores for each emotion, which is composed of recall and precision. The outcomes of these results are fairly similar to the outcomes of the recall of the emotions. The F-score of 'frustration' is only slightly (0.3%) higher than that of 'disgust', which has 44 instances less. 'Hope' has a higher F-score than 'conviction' (25.3 versus 19.5), while the latter contains 17 more instances.

Table 15 generally shows that more instances of a given emotion may result in a better precision, recall or F-score. Yet, this is not always the case as there exists also another important underlying factor, i.e. the lexicalisation of the emotions. Emotions that are generally more lexicalised may generate better scores. Consequently, the system may need less instances to build a good-working

model. Many of the emotions in this corpus are lexicalised but the way in which they are lexicalised differs (see 4.1.8). 'Indifference', for example, does not show a strict pattern as emotions words in the instances differ a lot from each other. Emotions that have a more recognisable pattern, such as 'admiration', tend to have higher scores. Nevertheless, this is not always the case as some lexicalised emotions with recognisable patterns do not have precision, recall, or F-scores. This is the case for 'love' which was often annotated with 'love' or a derivative word, but was not indicated correctly by the system. Nevertheless, the low scores for 'love' may be due to the low frequency of this emotion in the corpus.

4.2.2 Confusion-matrix

	Fear	Frustration	Admiration	Conviction	Sadness	Joy	Anger	Regret	Hope	Disgust	Indifference	Surprise	Satisfaction	Doubt	Love	gratitude
Fear	4	11		5	2	2			3	6						
Frustration	3	61	4	17	4	5	7		5	29						1
Admiration	1	9	1	3		1	1		1	1	3					
Conviction		24	1	15	1	3	2		10	11						1
Sadness	2	7		6	4	1			2	6						
Joy	1	11	2	6		3	1		1	6						
Anger	1	12	1	5	1	3			1	6						
Regret		1		1												
Hope	3	16	1-	9	3	3			12	7						
Disgust		32		12	1	3	5		2	36				1		
Indifference		3			1											
Surprise	2	9				1			2	4					1	
Satisfaction		3		2						1						
Doubt			7		1				1	1						
Love		1	1	1		1										
Gratitude		5		1					1							

Table 16: Confusion-matrix

Table 16 gives an overview of the spreading of the emotions that were indicated by the system. It shows which emotions the system confused with other emotions and how often. The top-bottom part of the table shows the known classes of the emotion and from left to right are the emotions that the system indicated and how often. 'Fear', for example was 4 times indicated correctly as 'fear', 11 times as 'frustration' and so on.

Sometimes, the system confuses emotions that are closely related to each other. 'Fear' was confused with 'frustration', 'sadness' and 'disgust', which are all negative emotions too. Nevertheless, it was also indicated as 'joy' twice and three times as 'hope', which are generally rather positive and thus opposite emotions. Thrice, the system indicated 'fear' as 'conviction', which can be either sentiment. 'Frustration' has the highest number of correctly indicated instances, which was also clear from the high recall score in table 15.

All but one of the emotions ('doubt') are at least once confused with 'frustration'. Yet, none of the emotions was ever confused with 'satisfaction' or 'surprise'.

The system seems to have problems with some emotions. 'Conviction', for example, was more times indicated as 'frustration', than predicted correctly (24 versus 15). The emotion is also often confused with 'hope' (10 times) and 'disgust' (11 times).

'Joy' was more times indicated as a negative emotion, such as 'disgust' or 'frustration', than as a positive emotion. It was only three times indicated correctly.

Although 'anger' has a fairly large number of occurrences (40), it was not predicted correctly by the system. Most of the instances (12) were confused with 'frustration'. 'Disgust' was also often confused with 'frustration', and vice versa.

5. Discussion and Conclusion

5.1. Conclusion

Some conclusions can be drawn from the data and the charts in the results section. First of all, many of the tweets that were analysed, contained an emotion (98 %). It may be the case that many Twitter users mostly tweet when they want to convey their opinion about a certain topic, which results in a tweet that contains an emotion. Especially the topic of elections may generate more emotions throughout the Twitter public and leaves no one untouched.

From the tweets that contained an emotion, the sentiment in the largest number of instances was negative. The lowest number of negativity was found during the protests that erupted after Donald Trump's victory. During this moment positivity and extreme positivity were at its highest.

It is seen that the sentiment correlates with the emotions as generally negative emotions, such as 'frustration', are found with a negative or a very negative sentiment.

The two emotions that were the most conveyed throughout this corpus of political tweets were 'frustration' and 'disgust'. These two emotions alone, were present in 384 out of 893 emotions that were found in the corpus. This could mean that many Twitter users tweet something, not only when they want to convey an opinion, or an emotion, but often when that emotion is negative or conveys 'frustration' or 'disgust', too.

On top of that, as only 2 out 16 emotions ('frustration' and 'disgust') cover 43 per cent of the total number of emotions that were found in the corpus, other emotions are much less present. This is the case for 'regret', 'love' and 'indifference', which are only present less than six times. A similar pattern was found in the analysis of the separate moments in the corpus. Yet, 'hope', which normally covers up to 12.9 per cent of the moments, shows a strong increase (to 20 %) during the last moment. The last moment covers the protests that erupted after the announcement of Donald Trump's victory. This could mean that during that period many people were 'hopeful' that the protesters would succeed. Yet, this should be investigated more as this corpus is too small to draw such conclusions.

Surprisingly, 'anger' reaches its lowest percentage during the fourth moment, when the FBI investigation into the emails of Clinton was opened. 'Joy' was most felt on the morning of the presidential elections (15.4 %) and was hardly present during the protests (0.8 per cent). During the same moment, 'fear' reaches its highest percentage (11.7 %). 'Conviction', an emotion that can be either (very) negative or (very) positive, shows a very fluctuant pattern. Tweet authors had the most convictions about something or someone, when the election result was announced (20 %). Yet, on the morning of the elections, only 1.5 per cent of the tweets contained a 'conviction'.

The study also shows the difference between the emotions that are described in the models of Ekman (1992), Russel (1980) and Suet Yan and Turtle (2016) and how they are divided in the corpus. From the results it can be seen that, while Ekman had the model with the smallest number of emotions (in total six emotions), his model accounts for the highest coverage of our corpus (45.2 %). Yet, the emotion model of Russel adds the emotion that is most present throughout the entire corpus (i.e. 'frustration'). The emotions that were extracted from this model, however, only account for 36.1 per cent of the emotions found in the corpus.

The emotions that were used in the study of Suet Yan and Turtle (2016) account in total for 44.1 per cent of our tweet corpus. Nevertheless, the emotions that this study added to our emotion categories are only present in a small number of cases (less than 30 times). Only hope has a higher frequency (99 times).

Although the emotions of Ekman have the highest coverage in this corpus (45.2 %), this model only accounts for less than half of our corpus. This means that the other emotion models of Russel and Suet Yan and Turtle were necessary to annotate the corpus more profoundly.

During the annotations, the presence of irony also needed to be indicated. The results show that irony was not much present, only in 40 out of 546 instances that contain an emotion. Nevertheless, González-Ibañez, Muresan and Wacholder (2011), found in their study that sarcasm was difficult to detect by both humans and computers. As sarcasm and irony are very much alike, it cannot be excluded that more tweets contained irony but that this was not interpreted in that way by the annotator. The instances in which irony was indicated were mostly combined with the emotions 'frustration' and 'disgust', which were also the most present throughout the entire corpus.

Another element of the analysis is that of the favourability of a particular presidential candidate of the tweet author. In the large majority of tweets, elements were used that indicated that the author was 'not in favour of Donald Trump'. This result may be due to two factors. The first factor is the hashtags that were used to retrieve the tweets: as most of the trending hashtags at the beginning of this research were anti-Trump, this may have had an effect on Trump's favourability in the tweets. The second factor may be that the majority of Trump voters did not have a Twitter account which may result in more tweets against him. Nevertheless, more research on this is needed as the previous claim cannot be backed with suitable data.

Yet, the second most indicated option was that the author was in favour of him. This could mean that Twitter users were mostly either very much 'against Donald Trump' or very much in favour of him. 'Hillary Clinton' was much less present in the data, which could be explained due to the hashtags that were used to retrieve the tweets, which were all linked to Donald Trump.

The favourability was also linked with the particular moments. A surprising finding is that 'not Donald Trump' was the most indicated option for all of the moments, except for the moment during the protests. Then, most tweet authors were 'in favour of Donald Trump', which is surprising as the protests were against him winning the American elections. 'Donald Trump' was the least indicated option during the second moment, which indicates the release of the tapes. The favourability for 'Hillary Clinton' was at its highest after the announcement of the FBI investigation against her.

For each of the emotions, if possible, the target needed to be indicated. There was a large number of targets, but the most important for this study was 'Donald Trump'. Similarly to previous findings, 'frustration' and 'disgust' were the emotions that were most used to target the current President. Together, they cover 38 per cent of the emotions that were targeted against him. This could mean that the perceived or conceived reputation (Carroll, Greyser and Schreiber 2011) of Donald Trump amongst Twitter users is rather negative. This result is in line with the result of the favourability which indicated that most Twitter users in this corpus are 'against Donald Trump', which ultimately results in more negative emotions and feelings towards him. It could be said that these results are also in line with the election as it was Hillary Clinton and not Donald Trump that won the popular vote (CNN, 22.12.2016). This means that Donald Trump won less votes but eventually won the elections because he won the most votes in important states.

During the annotation process, the words that conveyed a particular emotion needed to be indicated. It can be seen that the emotions are very lexicalised in this corpus. Sometimes, general knowledge was needed to interpret the words on an emotional level (e.g. "Brexit ii" for 'sadness'). The fact that these tweets were mainly political tweets can be seen from words such as "fraud", "corruption", "hypocrisy", which were present with the emotion disgust. Negative words that were used to refer to Donald Trump are "homophobe" or words that refer to sexual assault or racism. "Crooked", on the other hand, was a negative word that was used with Hillary Clinton. The lexicalisation of conviction was often found with modals.

In the second part of this master's thesis a machine-learning system was built on the basis of bigrams. Although the system was built on a simple feature, the precision, recall and F-scores are generally promising, specifically for emotions with a high presence in the corpus. Emotions that have a lower occurrence tend to generate lower scores. This may be due to the 10-fold system, which makes it possible that, for some of the folds, all of the tweets of a certain emotion are present in the training corpus, but not in the test corpus, and vice versa.

The confusion-matrix showed that the system generally has problems with emotions that are closely related to each other, such as 'frustration' and 'disgust'. Nevertheless, sometimes emotions were confused with emotions that have no relation (e.g. 'joy' and 'frustration').

As no definite research was found that compared emotion detection on Twitter and reputation, it is difficult to highlight differences or similarities with previous work. Nevertheless, this work could be used to compare with future, more elaborate,, studies on emotion detection and reputation.

5.2 Discussion

The results that were found after the analysis of the corpus should be treated with some caution as the corpus only contains 556 tweets. This number is only a fraction of the tweets that are sent about Donald Trump each day. In addition, the tweets that were extracted for each particular moment were also too small to generalise each of the results. They can, however, be used to give an indication and may be fruitful for future research.

Another shortcoming of this research is that there was only one annotator, which is why no inter-annotator-agreement could be given. As this is only a master's thesis, there is not the same amount of funding as for other research. On top of that, the annotator should have a sound knowledge of English and the American culture, which made it more difficult to find a second annotator.

During the annotation process, it became apparent that for each of the tweets a high number of features needed to be indicated. In total, 19 elements could be indicated, which made the annotation process more difficult and especially more time-consuming. In addition, the annotator could choose from a list of 16 possible emotions, which might have been a too high number, given the small number of occurrences of some of the emotions (e.g. 'love', 'indifference' and so on).

On top of that, as was also indicated in the results section, the results on the division of the popularity between 'Hillary Clinton' and 'Donald Trump' should not be generalised. Therefore, unfortunately, we are unable to determine the (non)-popularity of 'Hillary Clinton' or provide a comparison between the two presidential candidates. The tweets of the corpus were retrieved on the basis of certain hashtags that talked about Donald Trump and not about Hillary Clinton, which may be the reason why less tweets in this corpus were in favour of her. Nevertheless, the combination of target ('Donald Trump' and 'Hillary Clinton') and the type of emotion that was most used can give an indication of the (non)-popularity of a certain candidate. For more conclusive results, however, the number of analysed tweets should be higher. During the analysis of the corpus, it became clear that there was a high number of implicit targets (104 in total), which made it difficult to provide a coherent analysis.

The system showed promising results for emotion detection. Nevertheless, some emotions are often confused with other emotions. Apart from the emotions being closely-related, this may also be due to

the fact that only the first emotion was used for this system. Therefore, it may be the case that the emotion that was wrongly predicted by the system was actually the second emotion that was indicated during the annotations.

Nonetheless, the results and the method of this research could be fruitful for further research. This research is one of the first on emotion detection and reputation which means that the line of research is not yet firmly established. There are a few elements that future research could concentrate on. First of all, researches should establish which emotions are universally used on Twitter and can or should be investigated in future research. Secondly, as many new developments have improved automatic sentiment detection, research should concentrate more on emotion detection as this gives more profound information about a tweet or another instance. Lastly, the field of research of reputation management should be combined more with that of emotion and sentiment analysis as the outcomes might generate useful information. The latter may result in the construction of a well-performing reputation monitoring tool.

7. Appendices

Appendix I: Guidelines for the annotation of tweets

7.1 Corpus

The corpus consists of tweets about Donald Trump that were retrieved on 7 decisive moments in the American elections and contain the following hashtags:

#NoTrump, #TrumpHate, #DumpTrump, #MakeDonaldDrumpfAgain, #LoveTrumpsHate, #NeverTrump, #LoveTrumpsHate, #DonaldDeplorable, #Trump, #MakeAmericaGreatAgain, #TrumpTrain, #TrumpPence2016, #TrumpRally.

The aim of this research is to investigate which type of emotion is expressed in each of the tweets. In addition, the sentiment (being (very) positive, (very) negative or neutral) and target of the instance will have to be indicated.

7.2 Emotion Expression

For each of the Tweets, it is important to indicate whether a tweet contains an emotion. If this is the case, choose 'yes'. Then choose the emotion that is conveyed in the tweet out of the following list. (Ekman 1993, Russel 1980, Suet Yan & Turtle 2016). Examples of each emotion are included at the end of this document.

- anger
- disgust
- joy
- surprise
- sadness
- fear
- frustration
- satisfaction
- admiration
- conviction
- doubt
- hope
- regret
- gratitude
- love
- indifference

Whenever possible, it is important to indicate the words that are linked with the emotion that was indicated. If this is not possible, the expression of emotion in the concerned tweet is left implicit, which will have to be indicated.

In addition, the emotion in the tweet may be weakened or intensified by the usage of certain modifiers. If that is the case, these modifiers need to be written down.

For example: “This is an incredibly beautiful house.” (The adjective beautiful is intensified by “incredibly”).

Finally, if a tweet contains irony, this will have to be indicated too.

For example:

Nice of #Trump to give #Hamilton such awesome promotion! :D :D Nothing like a lunatic President elect tweeting about u to get attention.

#Trump #Pence demand an apology from the Hamilton cast for exercising their freedom of speech. Great job protecting the constitution :)

The annotation procedure for emotions is the following:

1. Read the tweet
2. Indicate whether the tweet contains an emotion (‘yes’ or ‘no’)
3. If ‘yes’, indicate which emotion is expressed in the tweet.
4. If possible, indicate the words or phrases in the tweet that convey that emotion.
5. Choose ‘yes’ in the column of implicitness if there are no such words.
6. If possible, indicate the modifiers that weaken or intensify the emotion.
7. Repeat steps 3-6 for the next emotion (if necessary).
8. Choose ‘yes’ in the column of irony if the tweet contains an ironic statement.

7.3 Opinion Expression

The aim of the research is not only to see which emotion is conveyed in the tweets, but also to see which sentiment is conveyed. Therefore, the sentiment (positive, negative or neutral) needs to be indicated.

This sentiment is either positive, negative or neutral and can have gradations:

- Positive or very positive
- Negative or very negative

A tweet is considered ‘very’ when it contains an explicit modifier (see above), capitalisation or a punctuation mark (! or ?) which has an effect on the strength of the sentiment.

The annotation procedure for sentiment is the following:

1. Read the tweet
2. Indicate the sentiment that is expressed in the tweet (positive, negative, very positive, very negative or neutral)
3. If possible, write down the modifiers that intensify the sentiment.

7.4 Practical

Annotations will be performed in Excel

7.5 Emotion examples

The following with examples of each of the emotions with a non-exhaustive list of possible indications of that emotion.

Anger

#USA likes to call itself most forward thinking nation, yet could potentially elect #trump a #president.

Three words. FUCK RIGHT OFF.

Possible indications of anger

- capitalisation
- exclamation mark
- swear words
- mostly about a situation

Disgust

#Trump is a hypocrite who doesn't manufacture his products in America. He has his best interest at heart, not America's, not the planet's.

Possible indications of disgust

- mostly about a person
- usage of negative words or swear words such as 'crooked', 'xenophobic', 'racist', 'misogynist', ...

Joy

Early voting shows upsurge of women. Women voters are coming out in force to vote against #Trump
Good! #nevertrump

Possible indications of joy

- usage of positive words such as 'good', 'wonderful', 'delighted, ...

Surprise

Hillary Clinton got the most votes and came second to the man who said the election is rigged. Work
that one out #Election2016 #Trump

Possible indications of surprise

- contradiction in the sentence
- usage of words such as 'surprised', 'astonished', 'amazed', 'dazzled', 'bewildered', 'staggered'
or other synonyms.

Sadness

I know you think retweeting #Trump's posts is funny, but please know, he's being serious. After a while,
that stops being funny. :(

The #Trump family .. burying the last remembrances of American Democracy! :(

9/11 was a dark day. In the US, it generally refers to 11 September. In the UK we know better: It's 9
November: #Trump victory day. :(

Possible indications of sadness

- usage of sad emoticons: ☹ and :(
- usage of words such as 'sad', 'depressed', 'sorry', 'unhappy', ...

Fear

Another hour closer to the time that #Trump gets elected and the #USA falls apart.

Possible indications of fear

- usage of words such as 'anxious', 'fear', 'worry', 'frightened', 'concerned' or other synonyms
- fear for something that might happen in the future

Frustration

When 47% of Americans did not vote what did they or we expect? #USAPolitics #auspol #Trump

Goddamnit! That fucker got away with it #Trump just settled the fraud lawsuit for 25M. :(
#NotMyPresident hello darkness

Possible indications of frustration

- usage of swear words or words such as 'unfit' and synonyms.
- a certain situation that is found to be untrue or unjust.

Satisfaction

#debatenight prediction: #Trump bows outta future debates --- or bows outta race. Either way, I am satisfied.

Possible indications of satisfaction

- usage of words such as 'satisfied', 'content', 'fulfilled' or other synonyms

Admiration

I give Trump so much credit He's only one person and he's up against everyone #Trump Train Full Speed Ahead #VOTE TRUMP NOV 8 #FREE AMERICA

Possible indications of admiration

- usage of capitalisation
- usage of words such as 'admire', 'adore', 'applaud', 'appreciate', 'credit', 'honour', ...

Conviction

The criminal marxist regime of #Obama is waging an undeclared war on local police. Donald #Trump will end that war.

Possible indications of conviction

- modal verbs (e.g. should, would, must, ...)
- strong belief or opinion about someone or something

Doubt

I doubt Reid HAS any exercise equip but even if he did, a danger if he spoke out about HRC.#Trump uses words not violence #MAGA #USA

#Trump believes it's O.K not to pay workers if he is not satisfied by their work. I am not sure it's promising concept for USA in his hands

Possible indications of doubt

- usage of words such as 'doubt', 'hesitate', 'imagine', 'disbelieve', ...
- if-clause

Hope

Don't mourn, don't run: ORGANISE, MOBILISE, RESIST Not my President!": 1000s of #US #protesters on streets #Trump

I hope that the #Trump #Nation will be more a #BUM nation than an #abomination or an aboli-nation :(

Possible indications of hope

- usage of words such as 'hope', 'wish', 'pray',...
- hope for a better situation

Regret

When you realise the first guy you had a crush on really IS a moron.. :(

Possible indications of regret

- usage of words such as 'regret', 'lament', 'repent', ...
- doing something that turns out differently than expected

Gratitude

Thank god the #rothschilds didnt get their puppet! Well done #Trump for keeping that evil corrupt bitch #clinton out of the Trump House!!!

What I'm Thankful 4 other than Jesus & my family, is #Trump I believe he's Gods choice for r country So STOP the chaos & #MAGA

Possible indications of gratitude

- usage of words such as 'thank you' (or another person), 'thankful', 'praise', 'bless', 'appreciate', 'bow down' for someone, 'well done', 'good job', ...
- usage of an exclamation mark

Love

I just love how #Democrats always say "Most Americans" don't like #Trump & his #CabinetPicks The Truth is Most Americans voted 4 him 2 #MAGA 1 reply 0 retweets 0 likes

Possible indications of love

- usage of words such as 'love', 'worship', 'idolize', 'treasure', ...
- close to admiration but stronger

Indifference

I'm indifferent to this whole election. As long as our communities work together it won't good or bad
#TRUMP #ElectionNight #TrumpPresident

Possible indications of indifference

- usage of words such as 'indifferent', 'aloof', 'apathetic', 'uninterested', 'disinterested',

Appendix II: Description of the corpus

The following appendices are 'Appendix III: test corpus' and 'Appendix IV: corpus with annotations'. These appendices are a long table with the annotations that were made for the test corpus and the eventual corpus. The tables are very wide and may sometimes contain words that are not abbreviated correctly, since the cells are sometimes too small for the text they contain.

Emotions, sentiment and yes/no answers were not textually inserted in this table but changed to numbers to have more space for other textual elements in the table. What follows is a list with a short explanation of the features that needed to be indicated as well as an explanation of the numbers that are used for each column.

Column 1: number of the tweet

In this master's thesis several examples of tweets in the corpus were used, which were indicated with their number in Appendix IV. The numbers make it also possible to see the division between the seven moments in the corpus.

Moment 1: 1-77

Moment 2: 78-159

Moment 3: 160-240

Moment 4: 241-320

Moment 5: 321-401

Moment 6: 402-482

Moment 7: 403-556

Column 2: tweet

The second column contains the original tweet.

Column 3: emotion?

The third column contains either a 1 ('yes') or a 2 ('no') to indicate whether the tweet contains an emotion or not. If it was found that the tweet contained no emotion, the tweet was not further annotated.

Column 4: first emotion

The fourth column contains the number of the first emotion of the tweet. In total, there are sixteen emotions:

'fear'= 1,	'gratitude'=9
'hope'= 2,	'frustration'=10
'disgust'=3	'admiration'=11
'indifference'=4	'conviction'=12
'surprise'=5	'sadness'=13
'satisfaction'=6	'joy'=14
'doubt'=7	'anger'=15
'love'=8	'regret'=16

Column 5: words first emotion

Column 5 contains the words or phrases that indicated the emotion in the tweet.

Column 6: target first emotion

In column 6 the explicit target of the first emotion can be found.

Column 7: implied target first emotion

Whenever the explicit target of the tweet was not entirely clear, due to a certain hashtag or metonymy, the implied target of the first emotion was also mentioned.

Column 8: implicitness first emotion

Column 8 can contain either a 1 ('yes') or a 2 ('no') to indicate whether the emotion in the tweet was conveyed explicitly or not.

Column 9: modifiers first emotion

If the emotion was made stronger or weaker due to certain modifiers, these needed to be mentioned in the ninth column. These modifiers can be words, but also exclamation marks or question marks.

Column 10: second emotion

Often, a tweet contained a second emotion, which needed to be annotated in column 10. The list of the numbers that correlate with a certain emotion can be found under the description of column 4.

Column 11: words second emotion

In this column, the words that convey the second expressed emotion are mentioned.

Column 12: target second emotion

The twelfth column mentions the target of the second emotion that was explicitly mentioned in the tweet.

Column 13: implied target second emotion

The implied target of the second emotion can be found in column 13.

Column 14: implicitness second emotion

If the emotion in the tweet was conveyed implicitly, this column will show a "1" for 'yes'. If the emotion was conveyed explicitly, a "2" for 'no' was written in this column.

Column 15: modifiers second emotion

The modifiers of the second emotion can be found in column 15.

Column 16: irony

If a tweet contained irony, the cell in this column will show a "1" for 'yes'. If the tweet did not convey irony "2" ('no') can be found in the cell.

Column 17: first sentiment

The first sentiment of the tweet can be found in column 17. The numbers that can appear in this column are the following:

'Very negative'= 1

'Negative'= 2

'Neutral'=3

'Postive'= 4

'Very positive'= 5

Column 18: second sentiment

The second sentiment of the tweet can be found in this column. The number-word combination is written in the description of column 17.

Column 19: words first sentiment

This column contains the words that convey the sentiment that was indicated in column 17.

Column 20: words second sentiment

Column 20 features the word that conveyed the second sentiment (column 18).

Column 21: favourability

The last column gives an indication of which candidate the author of tweet most likely voted for. This favourability was inferred from certain textual elements in the tweets, such as hashtags (#TrumpPence2016; #MakeAmericaGreatAgain; #CrookedHillary). Sometimes tweet authors were not explicitly in favour of a candidate, but did show strong indications that they were not in favour of a candidate. Sometimes the tweet author was not in favour of either candidate. This was annotated with 'none'. A few tweets did not convey clearly enough the favourability, which was then annotated with 'not clear'. Here too, numbers were used instead of words:

'Not Donald Trump'= 1

'Donald Trump'= 2

'Not Hillary Clinton'= 3

'Hillary Clinton'= 4

'None'= 5

'Not clear'= 6

Appendix III: Test corpus
